

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

Zymotic disease, deaths

ORIGINAL PAPERS.

OUR CANAL POPULATION AND THE CANAL BOATS ACT OF 1877, AND THE AMENDING BILLS OF 1881, 1882, 1883, 1884.

By GEORGE SMITH, of Coalville.

FOR more than a century our canal-boat toilers have roamed over the country with their floating homes, carrying goods and spreading disease and immorality, which have, in sadly too many instances, left unhealthy influences on their track.

The science of sanitation and the blessings of education were, and are still, almost unknown to our canal-boat workers. It is fearful to contemplate the amount of infectious diseases that have been carried from town to town and village to village during the last century.

Within the last few years 2,000 deaths took place in a very short space of time in one of our large towns, which disease, the medical officer of health said, was introduced to the town by a canal boat; in fact, it is to be feared that hundreds, if not thousands, of deaths have taken place since the passing of the Canal Boats Act of 1877 by infectious diseases, that have been carried to various parts of the country by canal boats and travelling tents and vans.

A boat from Staffordshire, with several children having small-pox on board, was for some days last summer among a number of boats, upon which and round them there were some hundred men, women, and children, of all ages and sizes, at Lower Heyford Ironworks, and unchecked by either the sanitary inspector or doctor until brought to bay by Mr. Collins, the manager. How long it had been moving to and fro among the boats in the Staffordshire and other districts before it arrived at Lower Heyford I could not learn.

A few months ago I came upon a boat at Brauston in which there were five children fearfully ill of fever. In addition to the five children there were a man, woman, and a 'chap.'

Recently a boatman lay ill of a most dangerous fever in a cabin in Staffordshire, and while he lay there his wife was confined of a baby by his side.

Within the last few weeks a canal boat carried small-pox from Worcestershire to Gloucestershire; and, more recently still, it has been conveyed from near London to some of the midland towns. In the boat there were man, woman, 'chap,' and five—some say six—children. The woman, instead of stopping at her cottage home in the country, as she could afford to do, and educating their children, had preferred to huddle together in the cabin, not six feet square, and to put their linen out to be washed where small-pox was at work; and it is to be feared that, in defiance of the Canal Boats Act of 1877 and all sanitary and educational laws, the seeds of this dreadful disease will be producing a crop of work for the doctors and sanitary officers where it is the least expected.

After some years of hard work and agitation, with a view to secure the education of the canal children, and the placing of their floating homes under proper sanitary laws, and also to prevent the fearful amount of promiscuous huddling together there is in the

cabins of both sexes and all ages, the Canal Boats Act was passed, based on a memorial I drew up in 1873, and which was signed by seven boatmen, only one of whom could write his own name, and is as follows:—

'We, the undersigned, think and speak, from conversations we have had with other boatmen, that no child under thirteen and no female under eighteen years of age should be employed on or allowed to sleep in canal boats. The cabins should be so made as to allow of proper ventilation, and not less than 100 cubic feet of space for each person. Power should be given to the workshop or sanitary authorities to enter a boat at any time, and either detain or order to be removed any person suffering from infectious diseases on board. The name of the owner, the number of the crew, and date when last examined by the inspector should be painted in a prominent place on the boat. Our children ought to be educated and protected as children on other work are. We regret to think that not more than two out of every 100 under the age of fourteen can read or write, and not more than five out of every 100 attend a place of worship on Sundays.'

After no little amount of trouble I succeeded in inducing the Government, in 1875, to allow the Royal Factory and Workshops Act Commission to inquire into the condition of our canal population; the chairman being Sir James Fergusson, vice-chairman, Lord Frederick Cavendish, and the secretary, Sir George Young. The result, after hearing a mass of evidence from boatmen, boatwomen, canal proprietors, agents, factory inspectors, magistrates, and others, was that they recommended in their report that no women and children should be allowed to live in the cabins at all, which cribbed homes, I say most certainly, were never intended to be sleeping quarters for more than two or three men or youths. So long as the canal traffic was chiefly in the hands of the canal proprietors, the evils of huddling promiscuously together had been fairly kept under control by pressing their own regulations. Now the canal proprietors concern themselves more about the traffic itself than the people engaged in it, and have, as a consequence, lost all moral control over the boat people, as the boats are no longer owned by them. This state of things opened the cabin doors for the women and children wider than they had ever been before—the boatmen not caring to shut them—with a sad result not only easy enough for a child to see, but a result that has told its tale upon the country, and upon the boatmen themselves. We may shut our eyes to the fact; nevertheless, the fact remains, viz., that the boatmen and their families of to-day are not so healthy as the boaters of the past generations. Disease is more rife among the children, bottles of physic are more frequently called for at the chemists, as they move through the country, and the hoarse, gruff cough and voices are more noticeable among the women than formerly.

An English narrow canal-boat cabin is about 8 feet 6 inches long, 5 feet 6 inches wide and 5 feet high, and is the floating home of a boatman and his wife and three, four, five, or six children of both sexes and all ages and sizes, with a 'chap' frequently into the bargain.

In this little space boaters are born, live, and die; and it is in this *little place* that nearly all their larder, kitchen, parlour, and bedroom requisites are stored.

The foul, poisonous atmosphere arising from the boatmen and their families when they are crouched in their *little beds* is at times, as they have often told me, 'enough to poison pigs.'

It is only fair to say that some of the boaters are as respectable as any other class of workers, and their homes as 'clean as pinks.'

The appearance of our boating population, taken as a whole, presents the features more marked, especially among the children, than when I first became practically acquainted with the boatmen and their families, some forty years ago; that is to say, the stout, strong and healthy boaters are not so numerous as formerly, and their places are being filled up on the one hand by the thin, poor, haggard, careworn and dejected creatures.

To my mind the two main causes of this are, first, the unhealthy state of the cabins and want of proper ventilation; second, working in their damp clothes—for the women and children have no convenience to dry them when they get wet; and, thirdly, to the amount of drinking they indulge in; for on an average throughout the country a boatman will spend six shillings per week in beer. But the question which arose in my mind whenever thinking the subject over during a lifetime of observation, but more especially since I began the agitation in 1872, was how to get rid of the evils surrounding boating life.

My long experience has taught me this: if action is taken wisely, two of the evils can be dealt with by laws that are applicable to the rest of the community; in fact, they have been slightly applied by the powers that are already in the Canal Boats' Act of 1877, but not so much as is desirable. Overcrowding in the cabin continues, and the education of the children is an object not yet accomplished. The third evil must be got rid of, chiefly, by moral and philanthropic agencies and influences.

Inspection under the Act of 1877 is little better than a farce. Some of the registration authorities of the Local Government Board have taken no steps to carry out the Act of 1877. Others have appointed officers to see to it, but have not given any salary for doing the work. That part of the work, namely registration, for which the sanitary authorities have received a fee of 5s., has been partly carried out. Eight thousand boats have been registered, with many thousands to follow, which registration, if the system of registration I recommend is not continued, so as to be able to tell who owns the boats and the names of them who live in them, will be worse than useless. The local inspectors appointed by the registration authorities have come from the ranks of policemen, surveyors, medical officers, and sanitary inspectors, and some sanitary authorities have been appointed registration authorities against their wish. Thus it will be seen that the system of inspection at present carried out is all 'heads and tails,' 'topsy turvy' fashion, and in anything but a satisfactory manner. Carelessness, apathy, and indifference have run through the inspection and everything connected with the Acts from the day it came into operation to the present time. With these failing points and difficulties staring us in the face, it has become an imperative and absolute necessity that, if the little good that has been gained by the Act of 1877 is to be maintained, the seed sown to bring fruit, and the fabrics, which are to be an ornament to the land, reared upon the foundations laid in 1877, the close upon 30,000 canal children educated—not

10 per cent. of whom can read and write—the spreading of disease stopped, habits of sobriety, morality, and industry encouraged, the Act of 1877 must be amended on the lines I have laid down in the Amending Bill, and described in my works and in my evidence before the select committee on canals last year—a Bill which has been before Parliament during the last three sessions.

Last year the Bill was read a second time, and referred to the Select Committee on Canals, and they reported it back to the House of Commons without amendment. As the Bill now stands it has been read a second time this year and referred to a select committee. Each year the Bill has been 'blocked' at the instance of the Canal Association on the plea that it will interfere with canal traffic. This I deny most emphatically. The carrying out of the Act on the lines of the Amending Bill will give an impetus to canal traffic, and bring health and happiness to the toilers.

The failing points of the Act of 1877 are—1. The Act, to a great extent, is permissive. 2. Proceedings cannot be taken against boatmen and boat-owners for breaches of the regulations. 3. The Act is placed entirely in the hands of the local authorities, which are, as a rule, twenty, thirty, forty, and fifty miles apart. 4. The non-annual registration of the boats. 5. The want of power in the Act to enable the Local Government Board to appoint officers to supervise, control, enforce, and report to Parliament the working of the Act, and to visit the boats working between the registration districts. 6. The want of power to enter the boats at reasonable times to inspect them. 7. The want of power to give the education officers power to enter a boat cabin to see to the education of the children. 8. The payment of a week's fees demanded from boat children who can only attend one or two days in the week. 9. Many boats, in coal and other districts, escape registration and inspection on the plea that the boats are not used as dwellings. 10. The fines, instead of being paid to the county fund, should be paid to those who institute proceedings and do the work. 11. There is no provision made in the Act or in the regulations for the transfer of boats by sale or otherwise. My Bill remedies these faulty places.

Clause 1 provides for the annual registration of the boats, upon which the success or non-success of the Act of 1877 and the Bill I am promoting depends, and I propose at a cost of not more than five shillings. At any rate, if the boats are not registered annually they must be registered every time a change takes place in the captains or masters, which would be a troublesome and an expensive affair, owing to the frequent changes taking place, often several times during the year. Nor would it be wise and practical to put a canal boat and her cabin crew through the same forms, ceremonies, and difficulties that ships and ships' crews have to undergo every time a change of ownership and crew takes place.

The process I propose is both extremely simple and inexpensive, no matter in what part of the country the boat happens to be at the time of the annual renewal of the registration certificate. I will only take one case to illustrate my meaning upon this point. Suppose a boat is registered at Paddington in the first instance, but at the end of the year the boat is working on the canals near Birmingham. To compel the boat to be brought from Birmingham to Paddington for the renewal of the

gistration certificate would be a great and unnecessary hardship inflicted upon boatmen and at-owners. What the captain would have to do would be to ask the registration-officer at Birmingham to examine his boat, and, upon its being satisfactory, he would give the captain a note to that effect, which note the captain would send to the Edington registration officer, upon which the officer would forward the proper certificate of renewal registration.

Up to the present time the Local Government Board have had no power to enforce the carrying out of the Act of 1877. All they could do was to make regulations, which the Manchester and other authorities say, in effect, are not worth the paper they are printed upon. Clause 5 of the Amending Bill gives the Local Government Board and the Education Departments power to see that the Act of 1877 is properly carried out, and is as follows:—

1. The Local Government Board and Education Department shall from time to time cause inquiries to be made as to the due observance of the enactments contained in the principal Act, and in the regulations made thereunder, with respect to the registration of canal boats, the education of children dwelling on board canal boats, and other matters relating to the execution of the principal Act and this Act.

2. Every inspector of the Local Government Board and Education Department shall, for the purpose of any inquiry under this Act, have in relation to witnesses and their examination, the production of papers and accounts, and inspection of places and matters required to be inspected, similar powers to those which poor law inspectors have under the Acts relating to the relief of the poor for the purposes of those Acts, and power to enter any canal boat at all reasonable times.

3. The Local Government Board and Education Department shall, as soon as practicable after the meeting of Parliament in every year, cause to be laid before both Houses of Parliament a report as to the proceedings of inspectors appointed under this Act, and generally as to the execution of the principal Act and this Act.

4. Such part of the fees paid in respect of registration under the principal Act and this Act as the Local Government Board from time to time direct, shall be applied towards the expenses of inquiry made under this Act.

Instead of the sanitary authorities doing the work, and finding the necessary money to enforce the provisions of the Act and the regulations of the Local Government Board, without any power over fines, Clause 10 of the Bill is intended to put the matter right and reads as follows:—

1. One half of any fine recovered under the principal Act or this Act shall go to the informer, and the remainder to the sanitary authority (as defined in the principal Act) of the district in which the offence is committed.

2. Provided that where the sanitary authority are informers they shall be entitled to the whole of the fines recovered.

3. All sums payable to a sanitary authority under this section shall be paid over to their treasurer, and shall by him be carried over to the account of the Local Government Board applicable by the authority to the purposes of the Act.

Clause 11 of the Canal Boats Act, 1877 (Amendment), Bill, deals with our gipsies, van, show, and other travelling children and their homes, and reads as follows:— 'The expression "Canal Boats," "Canal Boat," and "Boat," in the principal Act and this Act, and also in the regulations of the Local Government Board and Education Department, shall include all travelling and temporary dwellings not rated for the relief of the poor.' It was stated to the Committee that vans and like places are not canal boats, to which I replied that the principles involved and objects sought are the same; and the same machinery from beginning to end would have to be brought into motion to carry out the plans I propose. It is only a question of the term used or name given. In one case a home moves upon water, and in the other case a home moves upon land.

A thousand things far wider of the mark and object are brought under various acts of Parliament. Take, for instance, the wide scope of our factory, mining, and educational laws, or hundreds of other Acts of Parliament that are placed upon the statute-book.

It is time our canal and canal-workers were put upon a satisfactory basis, and if the boatmen do not get sufficient money to make them comfortable homes on land, it is high time they did, and this can be done by lowering canal tolls, increasing canal traffic, making canals of greater depth and width, capable of carrying boats of from two to three hundred tons burden—in the way I have indicated for many years—and the putting of the whole of the canal system under proper supervision and control, as other industries are.

Prayers and sighs have gone to St. Stephen's from friends in all parts of the country—diocesan conferences, Birmingham, Manchester, London, and other school boards, borough corporations, and quarter sessions—in favour of the Canal Boats Act Amendment Bill. The Essex Quarter Sessions, composed of about 250 leading county gentlemen, including peers, lords, M.P.s, baronets, and squires, at the instance of Mr. Andrew Johnston and Mr. Pierce, passed a unanimous resolution in favour of the Bill, and with no further response from headquarters to their action and my long, long years of toil than 'Go thy way for this time, and when I have a more convenient season—session—I will send for thee.' Will it ever come? I begin to doubt it.

PENNY DINNERS FOR SCHOOL CHILDREN.—The Rev. W. Moore Ede, rector of Gateshead, has been trying the experiment of penny dinners for poor school children. The result of the first week's experiment was a profit of about seven shillings on nearly 500 dinners, and this, the rev. gentleman says, 'has not been obtained by placing the children on short allowance. They have had each day as much as they could eat; for, unlike *Oliver Twist*, they have been allowed to ask for more as often as they pleased. One boy was heard to boast that he had sent in his plate eight times, and five helps were common.' Mr. Ede suggests that the system of penny dinners should be established in connection with all our National and Board Schools, or, at any rate, those in poor districts, and he affirms that the scheme will be absolutely self-supporting.

At the last meeting of the Blaydon Local Board it was stated that there were a dozen cases of typhoid fever at Black Hall Mill, which arose from the deficient or polluted supply of water at that place. There was also a total absence of drainage.

THE COMMUNICABILITY OF ENTERIC FEVER.

By ALEXANDER COLLIE, M.D.

[Having received the appended query from a subscriber, we submitted it for reply to Dr. Collie, who has kindly gone into this important question at such length that we deem it advisable to publish the information sent in an independent form.—Ed. S. R.]

Being Sanitary Inspector of a large district I write to ask your opinion upon the subject of typhoid fever. Is it communicable *from person to person*? The District Medical Officer of Health is of opinion that it is. Poor Law Medical Officer of great experience here is also of that opinion; but a young doctor recently established sneers at the above opinions as being those of 'old fogies' of the profession, and states that in London hospitals—St. Bartholomew's, for instance—typhoid cases are habitually treated in the same ward with other patients. May I also ask if the majority of the profession—so far as you are aware—agree with the 'old fogies' or with the young lights?—I am, Sir, your obedient servant,
June 25, 1884. M. S. E.

DR. BRISTOWE probably expresses the opinion of the profession on this question when he says:—"It is admitted by most physicians that enteric fever is not in the usual sense of the term contagious; that it is not conveyed from one person to another person by the touch or by the breath; and that attendants on the sick rarely, if ever, take the disease from them; yet it is quite certain that the immigration of a patient suffering from enteric fever into an infected locality not unfrequently leads to an outbreak there." The phrase 'the usual sense of the term contagious' is somewhat vague, and it would be well if the precise meaning of 'contagious' in the *usual* and the *unusual* sense of the term were definitely determined. There is also some contradiction in the statement that the disease is not contagious, and 'that the immigration of a patient suffering from enteric fever into an uninfected locality not unfrequently leads to an outbreak there.' Why, if it be not in some way contagious? Further, the statement 'that attendants on the sick rarely if ever take the disease' can no longer be maintained in the light of recent experience. Take the Homerton Fever Hospital as an example. It has been open as a fever hospital for about eleven years, and during that time about thirty persons contracted enteric fever, twenty-eight of whom were attendants upon the enteric sick: one was a laundry woman, who collected soiled linen from enteric fever wards, and one was a nurse, the origin of whose case was doubtful. On this point the experience of the Homerton Smallpox Hospital is very curious. From Feb. 1, 1871, to Sept. 19, 1879, 6,771 cases of smallpox and 171 cases of scarlet fever had been treated there, and during the same time about 487 persons had been employed in attendance upon the sick and otherwise; but during all that time, a period of about nine years, no case of enteric fever had occurred among these 7,000 persons, a large number of whom, being young persons, were of the susceptible age. But on Sept. 29, 1879, the Homerton Smallpox Hospital was opened for enteric fever, and within six weeks there were two cases among the nurses who nursed it, followed by a third a little later, and by a fourth at the end of three months in the person of a

porter who bathed the male enteric patients. Feb. 7, 1880, the smallpox hospital was closed for enteric fever and reopened for smallpox; and from time to time there has been no enteric fever. Homerton Smallpox Hospital (Gayton). The experience of the Homerton Fever Hospital is essentially the experience of the other fever hospitals. Till the six years 1878-83 eight nurses and attendants contracted enteric fever in the London Fever Hospital; and during the same years seven nurses and attendants contracted enteric fever in the Homerton Fever Hospital. The Hampstead Hospital was opened for enteric and scarlet fever in October 1882. Very few cases, especially enteric, were admitted until the autumn of 1883, when the wards were fairly full. Then three arose, two amongst nurses who were nursing enteric patients, and one in a housemaid who frequented the enteric ward. The experience of Deptford and Stockwell is similar. Whatever then be the explanation, the fact that attendants upon cases of enteric fever contract the disease is beyond dispute. The experience of the general hospitals is similar to that of the special hospitals of which the following is a striking example.

'The Committee regret to inform the Government that during the latter part of the year seven persons were laid up with typhoid fever, one of whom unfortunately died. Although the drains of the hospital had been carefully inspected so recently as last spring, the Committee considered it desirable to have them again thoroughly examined. This was done on two separate occasions, under the direction of Mr. Yuill, a member of the Committee, who had great experience in such investigations, and Mr. Harvey, the architect, when powerful tests were applied to ascertain whether any defects existed, and the Governors will be glad to hear that no defect was found in the condition of the drains that could account for the illness of the nurses. All the persons who were laid up with typhoid fever had been engaged in nursing typhoid cases; and this fact seems to indicate that the opinion of the medical profession as to the non-infectiousness or non-contagiousness of typhoid fever may probably, in the course of time, have to be reconsidered.'—*Annual Report of Royal Free Hospital, 1883.*

Dr. Donkin and Dr. Sharkey record, in the *British Medical Journal* of Nov. 6, 1880, similar experience in respect of the Children's Hospital at Shaftesbury and St. Thomas's, and in the same number Dr. McNeill describes an epidemic of enteric fever which was imported into Colonsay and spread there in no other way than from person to person. French opinion is not less decided. Thus, after discussing the opinions of Leuret, Germain and Bretonneau, who all hold that enteric fever is contagious, concludes: 'It appears to me hence impossible, after what has preceded, to deny the contagious character of the typhoid affection at Paris, for there can be no doubt of the nature of the disease observed by M. Bretonneau, M. Germain and those who share their opinions. The symptoms observed by them during life, and the lesions observed after death, are the same as among the individuals attacked with the affection of which we are now speaking, "et comment admettre que la maladie soit contagieuse à Tours et à Châteaubleau, et ne le soit pas à Paris?"' Dr. Germain writes to the same effect:—"A considérer les rapports que l'Académie reçoit

the epidemics which prevail in the departments one that "la contagion de la fièvre est un fait acquis désormais à la science." enteric fever may be treated with safety to patients in the general wards of a hospital is this does not in the least show that it is not so, but only that in certain circumstances it is so. In particular, where the ventilation of the cubic space abundant, and the general precautions complete, it does not spread at distance; but that under such circumstances it does spread far is no evidence that it does not at all. By due attention to the conditions of typhus, enteric, and scarlet fevers are treated together with impunity; and when it is that the infective matter of the enteric fever is for the most part contained in his stools; these are passed into vessels which are immediately removed from the ward and emptied into the sewer remains nothing to infect the non-enteric in a general ward, and consequently there is no surprising in the fact that such patients do not contract enteric fever. It is quite otherwise with nurses. These are in close contact with the patient, have to remove their excreta, empty and wash bed-pans, collect and remove their soiled linen, and clean them, and move them about. Their position, therefore, in relation to the patient is entirely different from that of the other in a general ward, and the difference is only the fact that they *do* frequently take the disease they do so may not be quite so clear. And, moreover, be remembered that enteric is a disease of childhood and youth, and that consequently a large number of nurses are probably a previous attack.

S. ROBERT BOYLE & SON'S Patent Self-acting Air Ventilators have just been applied by the Admiralty to the drainage system at Sheerness Dock-dressers. Boyle have also recently applied their system of ventilation to the General Post Office, Liverpool; General Post Office, Leeds; Grand Hôtel de Alpes Maritimes; Albert Memorial Museum, Brixton Town Hall; Rochdale Free Library, Manchester; New Public Baths, Forest Hill; and the House of the Good Shepherd, Hammersmith.

SANITARIANS.—In the course of the discussion followed Dr. Corfield's paper on 'The Spread of Diseases,' read at the International Health Conference on June 14, Dr. Walford remarked that 'There is new in sanitation; the earliest medical officer, and perhaps the best, was Moses. The principles laid down by him were of the very best, though, naturally, they were better fitted for dwellers in tents than residents in large towns. (This aspect of the question was fully dealt with by Mr. Ernest Hart in his paper on Mosaic Sanitation, delivered some years ago at the Jewish Working-men's Club.) Dr. Walford pointed out that Cyrus fully understood the value of water, only drinking the produce of one particular spring that boiled.'

THE LANCET Parliamentary paper gives the number of cases found in the river Lea in the years 1882

In all, eighty-five bodies were found in the river during these two years, and the result of the coroners' verdict upon them was a verdict in thirty-five cases of natural death, in one of wilful murder, and in eight cases of death; while in forty-one cases no opinion was expressed as to the cause of death.

DRAIN-TESTING.

By HENRY MASTERS.

SOME few years since a letter appeared in a contemporary drawing attention to the importance of house-draining being free from leakage, and advising every one who had a drain in their house, to procure a certain quantity of ether and pour it down a sink or closet, and then, if any defect existed, the ether would escape and the defect be discovered. This amateur system of drain-testing took immensely with the public, and, I dare say, there was a run upon the ether market for a time, and even now I meet with people who have just tested with ether. The letter did good, for it taught the public that it was important that their house-drains should be sound and free from leakage. There are in England and Wales about 4,000,000 houses, and I should not be astonished that, if these were tested, at least 3,000,000 would be found defective.

Drain-testing by strong scents is not a new thing, for in my early days (nigh fifty years ago) I have a vivid recollection that if water in which cabbage had been boiled was discharged into the kitchen sink, its odour invariably escaped into the cellar, up the staircase, and, I dare say, the air of the reception rooms and bedrooms did not escape being highly charged with this vegetable test; but then in those days everybody considered it the right thing, if able, to have drains under their houses. As a matter of course, such drains must emit a bad odour, or how should a stranger be able to discover the locality of that useful appendage to a house—the water-closet. 'Follow your nose,' was the order of the day, and your nose seldom played you false. In these latter days we are more alive to defects in drains, and drain-testing has become quite a business, and consequently we have all our fads in this direction; one is strong for chemicals, another for smoke, another for filling with water, and another trusts to the sense of smell to detect the natural drain odour, and the latter class of testers are legion, and they are generally of 'opinion strong,' for, say they, if you cannot detect any drain odour the drains must be perfect. As I have for many years practised in each and every of these testings, I will give my experience, and in doing so I trust that I shall throw some light upon the question of drain-testing, for I find that some of those who ought to know are not all so well-informed as they should be.

I take rather a broad view of this drain-testing, for I do not believe that either of the systems enumerated above are applicable in all cases. Take, for instance, the case of an old house; you want to know if the drains are free from leakage, and your client will not hear of breaking ground, as he feels sure all is right, for he has constantly had traps put in. Now these traps are the rub. There is a trap at the closet and at the foot of the soil-pipe; another at the end of the passage, another under the cellar, another just out of the house, and another close to the common sewer, or cesspool. So here we have the drain divided into six sections, or pockets, and it is found that water passes freely from the water-closet to the cesspool, for you can hear it enter that receptacle by applying your ear to the bung-hole of the man-hole stone, or cesspool ventilator. To apply a smoke test in a case like this would be absurd, for the most you could do would be to try one or two sections through a sink or bung-hole, but if you put

carefully a strong peppermint oil, ether, aniseed oil, or nitro-benzole, and plenty of hot water to follow, the chances are you may fairly test the drain from end to end, and may find if this test has been effective by applying your nose to the bung-hole or ventilating pipe, and so discover if the test has gone from end to end. The advantage of the chemical test in such a case as I have described is that no trap in the line of the drain will interfere with its free action, for wherever the drainage flows the test will also flow, leaving particles upon the sides of the drain; so you have a long line of scent from closet to cesspool, and, if proper precautions are taken, you will be able to discover about the locality of the fault, if any.

If we have laid down new drains, and know where the traps are, there is no better test than smoke by the fan, and the machine made by Messrs. John

Watts & Co., engineers, of Bristol (who also supply test-paper), I believe to be the best in the market; at any rate I find it handy and effective, and, if packed in a box, is not a heavy package to travel with.

Water-testing has its limits, for seldom will a system of drains stand water pressure. Take a case; a small house has a 6" drain from back to front, is trapped at the sewer, has a scullery and a yard sink. The trap and sinks are plugged securely, and you let on the first-floor water-closet service pipe, until the basin is nearly full; all at once the water sinks, for something has given way; probably an underground pipe burst. You inquire into this, and find that the drains have been submitted to a pressure of about 12 lbs. per square inch. This upon the 6-inch pipe is more than 200 lbs. per inch run. To my mind this is a pressure that no drain should be submitted to, for drains are not made to carry high pressure water. It may be said that should a stoppage take place in the underground drain, everything should be strong enough to resist the water rising in the soil-pipe; but this can seldom, if ever, take place, for an escape at the scullery or yard-sink would at once draw attention to the stoppage. Water-testing is very well for a ware drain that has 3 or 4 feet rise, but nothing above that height should be filled with water, except the drain is of iron. There is this advantage in a water test—you fill the pipes and watch the effect; if it falls but slightly it shows that there is a leak somewhere; if they are tested before being covered up you can detect the spot; but if the drain is covered the whole must be opened and examined, for the leaking water will travel under the pipes for many yards and possibly be absorbed by the soil. Water-testing should only be tried upon new open drains, and after the cement-jointing is

well set. Some consider that a soil-pipe is tested by water—if the pipes are strong, well good; but I have a lively recollection of soil-pipe being so tested, and the lower end pipe gradually assuming a leeklike shape. In testing by water it is well to be provided with turned plugs of several sizes, about three long, covered with India-rubber. Some leather cups, with plugs of cork inside them.

Upon applying the smoke test it is necessary to take some precautions. All outlets (such as openings) should be plugged, and also the end of the drain should be cut off; for I have known when a strong current set in the direction of the main sewer, in which circumstances the smoke would be found to pass from the house into it. You must also regulate the quantity of material according to the capacity of the drain pipes to be tested, for a mansion will require more smoke than a cottage; and if you can cut a hole into the drain at several places, and cork one up, an examination of cork after cork will show you that smoke is present at certain points and disclose if the drain-pipes have been laid in pockets or accidental cesspools, caused by the layer allowing the pipe here and there to sink. In some cases you will find a difficulty in getting the pipe to make a hole into it. In such cases a gully or trap outside the house, or even the sink, extract all the water from the trap, sponge, and insert the smoke-pipe, bound with a duster or house-cloth, or a flexible tube, be passed through the trap water, and the water expelled by your breath. The great advantage of smoke-testing is that you can see, as well as smell, the exact locality of the leak, or at any rate you can follow the smoke to the defective part; it is of a strong flavour, flavouring the earth and not leaving a defect. In some cases I have known it leave a tint upon the earth. With the smoke test you do not require to be so careful of handling the apparatus as in chemicals, for touching a peppercorn will scent your fingers or dress, and will occasionally give a false scent; therefore too much caution cannot be taken in chemical testing.

The sketch herewith shows a suitable receptacle for carrying your chemical apparatus; it is divided into parts, the upper a Gladstone or other apothecary leather receptacle, and should contain a set of tools, viz., a square-faced and pointed back-saw, a logical hammer, useful for cutting a small hole in a ware pipe, and also as a centre punch

American drill, to make 3-16th inch holes in pipes; a square rimer; a screw tap, such as used by gas-fitters; a curved pipe, with taper ends, for fixing into a soil-pipe; several receptacles for chemicals, which may be screwed upon the curved pipe. These receptacles have taps at the bottom, and the contents are discharged in

pipe by opening the under tap first and the upper afterwards, and the chemical will pass down by

gravitation; but it may be advisable occasionally to screw a funnel on the upper end, so as to run some water through from a jug. This test is better applied out of doors, if possible, for it is next to impossible not to allow a small escape. Some lead or gutta-percha plugs, to screw into the pipe holes after you have finished; a screw-driver; a light hard chisel; a taper-piercer, to make holes in lead pipes; some nails, string and wax tapers; some slips of brown paper, which have been soaked in vinegar and saltpetre, for simple smoke-testing, such as waste-pipes, &c. There should also be some tin divisions, to contain two stoppered bottles, having a tablespoonful of diluted sulphuric acid in each, and about six 'torpedoes,' each charged with two ounces of oil of peppermint.

The lower part of the bag is a box, having a cover well secured and jointed with rubber, so that no scent can escape. This box should not be taken inside the house, and it should be fitted inside with tin divisions, to receive, say, two stoppered bottles, each to contain $\frac{1}{2}$ lb. of ether; two bottles, each to contain 2 ozs. Hotchkiss's oil of peppermint; two bottles, each to contain $\frac{1}{2}$ lb. of oil of turpentine (artificial almonds); a duster or two, and practice will perhaps suggest other tools, apparatus, and tests. With such a bag, fitted, you can commence operations; and first I should advise you to make an inspection of the whole premises, and take a rough sketch of the basement floor, noting by a X every sink, by a ● every soil or waste pipe, by O every rain-water pipe, and by dotted lines the supposed position of drains, underground tanks, bench marks, cesspools, &c., and the more notes you take the better. Examine all upstairs apartments, making separate sketch of closets, bath-rooms, and lavatories, with notes of fittings, water supply pipes, overflows, &c. You will be now in a position to commence testing, as you will have a fair knowledge of the scheme of drainage. At the same time, if you can get a local mason and plumber who have had something to do with the drains, they can give you much out-of-sight information which you will find valuable.

Having studied the various directions of the drains and pipes, endeavour to inject into each section a test of different odour; but, before commencing, all doors and windows must be closed, air-pipes and main drains stopped. Give your assistant full instructions, and keep him outside the house. He should be provided with the chemical box, several buckets of hot water, and a jug. Your position is inside the house, having previously provided yourself with what you require. Your assistant will drill the outside soil-pipe, or see that an outside sink is clear, and inject a test, which he washes down with hot water. If the test should be put in an outside soil-pipe, you can assist its development by pouring some hot water into the inside closet. Your next duty will be to enter each apartment, commencing near to where the test is applied, carefully closing each door after you; and if any test is discovered escaping, endeavour to find its exact point of escape, and make a note. You may find it necessary to try inside soil-pipes, because there may be traps top and bottom, and this may be done by putting down the closet a 'torpedo,' suspended by about a yard of string.

To describe the mode of testing in every case would far exceed the limit of this paper, but, like everything else, to be successful requires experience and a large amount of ingenuity, for the difficulties are many, and not least is having inaccurate smelling powers; and it is astonishing how defective the sense of smell is with some people. I have met with individuals who have failed to detect any scent even from oil of peppermint dropped into a glass of hot water, and again others who have scented out one's test-bag as it was taken through the house. A successful tester must, therefore, cultivate this important sense, so as to be able to distinguish the difference between one scent or another, and it is well to procure the use of any inmate's nose also, as it confirms your own opinion, and is evidence. A perfumer can tell to a nicety the kind of scent contained in a bottle or cake of soap, and their proportions, and I see no reason why drain-testers should not be able to distinguish the scent escaping into the house that his assistant has injected into the drain outside.

Another important matter in drain-testing is temperature. If the house to be tested be occupied and plenty of fires going, and the outside air at freezing point, the probability is that your testing will be very successful; on the other hand, should your test be applied to an empty house, and the outside temperature warm, very leaky drains may not be detected; in the latter case it is better to put off your testing till a more suitable day.

For chemical testing, Hotchkiss's oil of peppermint stands first on the list—dose, from one to two ounces—and it can be detected in the drain for twenty-four hours after it has been applied; next, sulphurated ether—dose, four to six ounces—this passes off in about four hours, and care should be taken not to allow a light to come near the ether, or for it to accumulate in pockets.

I tested the drain of one house with ether, and a fortnight afterwards a workman opened a cesspool into which the test had found its way, and upon striking a light to examine the cesspool, he was blown about three feet into the air, and had some slight burns; and a lady client once informed me that she had tested her own drains at night, by pouring into an outside sink a bottle of ether; the

result was that she was thrown some distance from the seat of operation, and her servant, who had the candle, ran for her life, and some light woodwork near took fire.

Nitro-benzole is a powerful test and retains its smell about as long as peppermint; it has a strong almond scent—dose, six ounces. Oil of aniseed is about the same character as murbane, but it cannot be successfully used in cold weather. There are other tests, such as oil of thyme and eucalyptus; but I find the above are sufficient for my practice.

In chemical testing great care must be taken not to be deceived by a false scent. If your assistant passes through the house after opening a test-bottle he may leave a trail behind him, which may be mistaken for an escape from the drain. A lady amateur informed me that she had tested her drains, and found them in a dreadful state. She poured a bottle of peppermint into an inside water-closet, and she traced the scent up her staircase and into every room of the house. The test of course passed through the closet door into the warmer atmosphere of the house, and so deceived her. A test properly applied in this case discovered no defect whatever.

In the upper bag I have suggested bottles with a little sulphuric acid in them. These are for taking samples of water from the pump, tap, or underground rain-water tank; and although I do not advise the readers of this paper to turn amateur chemists, I think they should have sufficient knowledge to be able to tell the difference between good and bad water, or to test in a simple manner the water they may find in use in a house they are called upon to inspect. If you get a sample of fairly good water, and put it into a test-tube with a drop of permanganate of potash, it will colour it a very light pink, and it should remain this colour for a day at least; but if you treat a sample of foul water in a similar manner it will immediately assume a yellowish colour, showing that it is not pure; and if such water as this be found in a house, the sooner an analytical chemist's opinion upon it is taken the better.

DISINFECTION OF RAGS. The Treasury Department of the United States has given the following directions for disinfecting rags imported into the United States from Egypt. They have been prepared after consultation with the Boards of Health of New York, Boston, and New Haven. 1. Boiling in water for two hours under a pressure of fifty pounds per square inch. 2. Boiling in water for four hours without pressure. 3. Subjection to the action of confined sulphurous-acid gas for six hours, burning one and-a-half to two pounds of roll brimstone in each 1,000 cubic feet of space, with rags well scattered upon racks.

DOMESTIC POISONS.—In a lecture recently delivered at the Health Exhibition, Mr. Henry Carr dealt with the dangers arising from the presence of arsenic in wall papers and domestic fabrics, to prevent which a Bill had been drafted, the provisions of which were not more stringent than those already in force in Germany, Sweden, and other countries. Owing to the investigations which had been made there had been already a great diminution in the use of arsenic colours, but the public needed to be reminded of the fact that green was not the only colour in which arsenic was to be feared. Several specimens of paper-hangings were exhibited in pairs representing arsenical and non-arsenical colours of very nearly the same shade. The two principal methods of testing for arsenic were next described in detail, and Reinsch's recommended for general use as being more easily carried out and sufficiently accurate for all practical purposes.

THE HOUSING OF THE POOR IN BIRMINGHAM AND THE BLACK COUNTRY.

(FROM OUR OWN CORRESPONDENT.)

[Sixth Article.]

THE newly-incorporated municipal borough of West Bromwich is one of the most pleasantly and healthily situated towns in the Black Country district. In some respects it has advantages which are not possessed by any other of the numerous parishes between Birmingham and Wolverhampton. Its altitude is high, it being in occupation of some of the highest table land in England. And although on the west and north it is subject to noisome fumes from chemical works and the black sulphurous clouds which belch from the throats of numberless forge and foundry chimneys, together with the choice atmosphere wafted from a couple of extensive gas-works, on the east the eye wanders over many a mile of pasture and woodland only limited in one direction by hills which bound the horizon, and in the other extending on the one hand to the metropolis of the Midlands, and on the other to the borough of Walsall. Over this wide expanse the population is very sparse; factories, foundries, and forges are unknown, and the atmosphere is as clear and pure as the landscape is full of natural beauty. Nothing more astonishes a stranger to the locality than to emerge from the lower parts of the town and behold stretched before him so extensive and beautiful a vision. Upon the slope of the town overlooking this scene lies a park of fifty six acres, given to the inhabitants by the Earl of Dartmouth, the Lord of Sandwell, of which estate it previously formed a part. In respect to the advantages we have herein mentioned, the inhabitants of West Bromwich are in a position to be envied by the many thousands of their less fortunately situated neighbours. West Bromwich is also fortunate in its High Street—one of the finest in England—and in its public buildings, all of which are ornaments to the town. It is not so fortunate in its sanitary administration, and however well its claims to be a prosperous and progressive town may be maintained in its commercial and general municipal relations, the claim to distinction fails when submitted to the test of sanitary science and sanitary advancement. Like most of the other towns in the district, it has been aroused to a sense of its shortcomings in matters appertaining to sewage disposal and purification through fear of the Rivers Pollution Prevention Act of 1876, with the penal enactments of which it has been threatened by its big neighbour Birmingham, on account of its pollution of the river Tame. Like most of the other towns in the district, also, it has turned its attention to the remedying of this evil, and has in hand a drainage and sewage purification scheme, which may, or may not, be in operation at the end of six or seven years. Like the other towns in the district, it has suffered from epidemic incursions of infectious diseases, and at the present time is under the sway of an outbreak of smallpox, which has maintained a more or less strong hold upon the place for more than a year and a half. All the neighbouring towns—Tipton, Darlaston, and Wednesbury especially—have been subjected to this dread scourge, and West Bromwich was about the last town in the district which succumbed. For some months it was

very virulent, and taxed the utmost resources of the place. When it first broke out here there were no means of isolation, and it was only after some months' delay, and by dint of strong pressure from without, that the sanitary department of the Corporation made such efforts to grapple with the disease as were likely to prove effectual. They hired a temporary building to serve the purpose of an isolated hospital; and took measures for carrying out long-delayed plans for the erection of a permanent hospital. After a while the disease began to flag, but it has never been thoroughly stamped out, and during the last few weeks has broken out again almost as badly as ever. It would not be wise, it might not even be correct, to say this was the result of any shortcoming on the part of the sanitary department. But there seems to be a generally felt and a frequently expressed conviction in the minds of the inhabitants that the work of that department is not so vigorously and effectually carried on as it might be, and that there is too apparent an inclination to underestimate the danger and neglect or dally with precautions.

West Bromwich is a municipal borough, with a population of about 60,000, situate between four and five miles from Birmingham, and between seven and eight from Wolverhampton. It covers an area of 5,710 acres, and its population is lodged in about 10,850 houses, giving a proportion of about five and a half persons to each house. In too many cases, however, especially in the small insanitary dwellings which are huddled together in the poorer and more thickly populated part of the town, it is no uncommon thing to find nine or ten persons in occupation of a three-roomed cottage. In respect to overcrowding, however, the town is in a much better position than its neighbours. The industries of the place include coal mines, iron foundries, hollow ware, and spring balance manufactories, nut and bolt works, &c. The water supply is derived from wells, and the mains of the South Staffordshire Waterworks Company. The latter is reliable; the former is generally otherwise. There is no system of drainage for sewage. The storm water and swill water from the houses runs along the street channels—where there are any—and is carried with the detritus from the roads into the watercourses and the canal. The open midden system—one of the most filthy and unwholesome systems of dealing with animal excreta in existence—prevails in all but the newest and better class houses, where the middens are covered and fitted with a ventilating shaft. There is probably no part of the district where more glaring instances of sanitary neglect and filthiness can be found, combined with inadequate closet accommodation and an absence of the requirements of decency and cleanliness. The regulation allowance of closets in all the more thickly-populated parts of the borough is one to three houses; in some places there is but one to four or even five. They are generally placed side by side, sometimes within a few feet of and facing the house door, occasionally a hundred yards or more away. Many of them have no doors, or had not until very recently, when an independent inspection of the borough with publication of the results directed particular attention to what in some cases was no less than a public scandal. The middens and ash-pits, generally combined, were found so full in dozens of cases that the liquid sewage was forced up through the bricks or flooring of closets, and lay in shallow pools on the surface or

trickled away down the yards, while the ashes and house refuse, overflowing from the inadequate or ruinous receptacle, formed a festering stinking heap in the open yard. It is no uncommon thing in some parts of the borough to see an open midden or cesspool standing in an exposed position in a yard, in some instances contiguous to a street, protected only by a few inches of brick wall. In one yard especially there is a green, stagnant pool, some feet in width, actually below the surface of the ground, unfenced and unprotected in any way from the children of all ages playing in the immediate vicinity. When a heavy shower of rain stirs up these fetid pools, especially after the contents have been accumulating for some length of time, the stench is something to be avoided. The removal of all this filth is carried on by nightmen, and every particle of it has in many cases to be taken through the house.

A few instances, taken from actual observation, will show the statements above made are not in any way overdrawn. The borough is divided into six wards. Greets Green Ward, which is on the lowest level, is one of the most insanitary. In one court opening into the main road are fourteen houses, containing between sixty and seventy persons, for the use of whom there are four small privies, with one open midden. In another court close by, the houses are arranged in the shape of the letter T. The privies allotted to these houses were some of them without doors, and the middens were in a very imperfect condition. In one street twenty-one houses open into one unpaved yard, in which are six closets. At the time of the inspection above referred to, the middens and ash-pits were so full that the liquid oozed up through the brick floors of the closets, and a great heap of ashes and house refuse had formed in the yard, where it had been accumulating for some weeks. In another street are two courts, the occupants of which were entirely without water for dietetic purposes, and had to rely upon rain water, which, even when properly filtered, is most unpleasant in flavour, owing to the smoke and fumes through which it has to pass. At the junction of two thoroughfares in this neighbourhood, the inhabitants of a row of twelve houses deposited their ashes and other house refuse, forming a heap neither agreeable to sight or smell. In another place, forming a thoroughfare between two main roads, much of the faecal matter seemed to be deposited on the surface of the ground, while a couple of cartloads of house refuse occupied a conspicuous position, and appeared to form a kind of playground for the children.

Abutting on the Greets Green Road—a main thoroughfare—were three cottages in process of demolition, the remnants of a row. Two of them were tenanted. More miserable tenements could scarcely be imagined, and yet a man and his daughter, employed at neighbouring brickworks, had lived in one or other of the row for forty years, paying half-a-crown a week rent. About fifty yards away were the remains of a closet, utterly unusable, and the functions of nature had to be discharged in the open. There were no back doors, nor any water-supply. One would think even the most supine of sanitary authorities would have had no difficulty in declaring such hovels unfit for habitation. A row of seven houses facing to the Greets Green Road, and opposite large ironworks, also have no backways. Their sanitary offices comprise two closets at one end of the row, reached direct from the public footpath,

from which they are shut off by a latched gate only. Faecal matter lies about the few square feet of space allotted to the occupants of these seven tenements. In another part of the same thoroughfare is a row of twelve houses, containing in all a population of some sixty persons, for whose use there were nominally three closets, all exposed to public view. Practically, however, the sanitary accommodation was restricted to two of these offices, one of them being without a door, within full view of a much frequented footpath and the towing-path of a canal, and also habitually used by the men and boys employed at some adjoining ironworks, a 'short cut' to which lies in immediate proximity to it. How can habits of cleanliness and decency, or even morality, be expected to be maintained under such circumstances? On the opposite side of the road is another row of ten houses, none of which have any back doors. The closets for the use of the people living here are situate nearly 110 yards from the end house, and can only be reached along the main road. There are four of them, two being without doors, and all within view of passers-by. The faecal matter runs away into a gully, where it stagnates or percolates into the ground. In another part of the same ward the liquid filth from the middens runs down the yard to a convenient spot at the back of a row of houses, where it forms a green, stagnant, stinking pool, percolating through the bricks and into the foundations of the houses, with results not pleasant to imagine. A large number of the houses in this and other wards in the borough are in bad repair, unspouted, damp, and internally filthy dirty. The landlords will not do anything to them, or even find the materials where the tenants are willing to apply them. The tenants cannot afford to whitewash and colour or paper the walls and ceilings at their own expense, neither can they remove to other quarters on account of being, very many of them, in arrear with the rent, and knowing that to attempt to 'fit' would be to run the risk of losing the few sticks of furniture they possess. Of course a great deal of the dirt and squalor and general wretchedness is owing to the uncleanly and intemperate habits of the people themselves, and in some cases to their fondness for live stock, pigeons and poultry of various descriptions being kept in close proximity to the houses, often in the houses themselves; it being no uncommon thing to find the only cupboard in the living room occupied at the bottom with coals, and above as a pigeon cot. In many cases, too, the landlords find their houses wilfully pulled to pieces, the quarries being torn up from the floor, and the woodwork from any place available, and used for various purposes. And as in some of the worst places they can neither get rent or get rid of the people without resorting to harsh measures, it cannot be wondered at that there should be a want of eagerness on their part to spend money on property possessed under such unprofitable conditions. A case in point occurred only a week or two since. A labouring man who, by dint of industry and thrift, had become possessed of several small houses in the central part of the borough, had them painted and done up, inside and out. Shortly afterwards four of them were tenanted by Irish people, and in a few days from that they became so infested with vermin that he had to expend several shillings on sulphur and carbolio soap, after getting rid of the objectionable tenants, before he could make them fit for anyone else to inhabit. Still, a great deal could

be done at comparatively slight cost by both landlords and the sanitary authority to remedy the more glaring evils. Great drawbacks to cleanliness and healthiness are the unsatisfactory state of the surface drainage, the damp condition of the houses owing to want of spouting and the existence of water in the cellars, the dilapidation and foulness which characterises so many of the privies and middens, and the want of a supply of pure water. We could multiply such cases of bad drainage and insanitariness as we have mentioned above by the dozen, did space permit. We have simply selected a few at random, and from one ward only, as showing the condition of things existing in a borough which claims—and with reason in some respects—to be in advance of many of the towns in the Black Country. In the more central parts of the borough, where the population is very dense indeed, the unwholesome conditions under which the people live are necessarily much aggravated. Little need for wonder is there that when a disease such as smallpox or scarlet fever breaks out, it spreads with alarming rapidity, and is very difficult to get rid of. It is some little satisfaction to find that the authorities are awaking to a sense of the responsibilities resting upon them, and that the work of the sanitary department is likely to be carried out in a more prompt, active manner in the future. One thing is absolutely necessary if any effectual improvement is to be made, and this is the increase of the departmental staff. Under such a condition of things as we have indicated, it will be readily understood to be absolutely impossible for one sanitary inspector to properly supervise a borough like West Bromwich. And yet up to the present time, there is but one such official. One cannot wonder that infected houses should remain in a neglected condition, and become centres of contagion for want of proper disinfection and cleansing, or that general and easily preventable insanitariness prevails to so large an extent.

THE BIRMINGHAM TOWN COUNCIL AND ARTISANS' DWELLINGS.

The report and recommendations of the Artisans' Dwellings Inquiry Committee—a summary of which was given in the *SANITARY RECORD* for June 16 formed the subject of a lengthy debate at a special meeting of the Birmingham Town Council held on the 24th ult. The mayor, in moving the adoption of the report, remarked that with regard to the sanitary condition of the houses, many had been cleaned and repaired to a considerable extent. The great difficulty in connection with the small houses in the future was that those rented at 2s. 6d. and 3s. 6d. per week were occupied by persons most of whom were not getting more than 1*l.* a week, and a consequence of condemning those houses would be to drive many of the people into the workhouse or to lodging-houses, and the remedy in that case would be worse than the disease. Many of the owners of this small property, too, were in as impoverished a state as the occupants, and to attempt to close their houses without giving them compensation would be exceedingly harsh. The difficulty was not in regard to the erection of new houses, for the building by-laws would prevent the erection on the same soil of defective property in the future; but in regard to the property put up before there were any such regulations. They were assured on all hands that the working classes were willing to pay

for a good house as much as 5s. to 6s. per week, and good houses ought to be provided at that rent.

Considerable discussion of a somewhat animated character followed, the report being ultimately approved, with the exception of the recommendations as to cleansing the courts and providing closet accommodation, which were referred to the Health Committee, with instructions to report their views thereon. The Improvement Committee are also directed to inquire how the principle of rent collection, as devised and carried out by Miss Octavia Hill in London, can be applied to the area under their control. The recommendations appended by the Artisans' Dwellings Committee to their reports have been somewhat adversely criticised, as but a lukewarm and half-hearted dealing with the question. They certainly do partake somewhat of the character of 'grandmotherly legislation.' There could be no doubt in the minds of any one who followed the evidence given during the inquiry that the generality of the courts were in a dirty if not an absolutely insanitary condition. Yet it is only suggested that the 'worst' courts shall be 'occasionally' cleansed by public scavengers. Such courts as exist in Birmingham, having many of them a large resident population, should be regarded as thoroughfares and submitted to the same treatment. They require it, as a rule, more than many streets and open thoroughfares. Undoubtedly there ought to be no qualification in so important a matter; whatever is done or left undone, every court in the borough ought to be lighted and regularly and thoroughly cleansed.

In addition to the physical and sanitary advantages, the moral effect upon the residents would not fail to be beneficial. People with cleanly habits find it difficult to practise and maintain them in the midst of filth; those who have not such habits will never acquire them under the conditions which too often surround them. The necessity for the recommendation as to handrails to staircases being rigidly carried out has been shown very recently by the death of a man through falling over a staircase without a rail, during a drunken spree on the night of his marriage. On the whole it cannot be said that the result of exhaustive inquiry has been the solution of that difficult social problem—What to do with the poor. The committee seem rather to have been content to shift much of their responsibility on to other shoulders, and the poor have to some extent to suffer for the municipal extravagance of the past, which prevents the Corporation, by reason of the emptiness of its coffers through 'daring enterprises, carried out with the most dazzling splendour,' from adopting practical and thorough reform.

We have now endeavoured, though in but a cursory and imperfect manner, to describe the conditions under which the poorer classes of Birmingham, Wolverhampton, and other populous parts of the Black Country district, live, move, and have their being. The sanitary and social conditions are alike deplorable, and one is often the result of the other. One cannot wonder much at drunkenness, cock-fighting, dog-fighting, and even prize-fighting being indulged in as often as possible, where so large a degree of brutality and ignorance and vice in its most ferocious form exists. Nor can these be swept away by all the moral and suasive influences brought to bear, until the dwellings of the masses and their surroundings are less filthy and less hostile to all notions of cleanliness, decency,

and morality. The home has no attraction; the man seeks attraction elsewhere. The conditions under which he is compelled to live will often not admit of the cultivation of self-respect, unless it be inherent in him, and many people soon cease to trouble about keeping the house clean and tidy, where everything around them is suggestive of all manner of filth and nastiness. A great responsibility rests upon local authorities in this matter alone. Let them set the example of cleanliness and decency in regard to the dwellings and their surroundings. The occupants, however poor, will soon follow it, and the moral, as well as the physical and sanitary well-being of the people will be considerably enhanced.

SANITARY BUILDING LAWS IN NEW YORK.*

By CHARLES F. WINGATE, Sanitary Engineer.

UNDER its English charter New York possesses almost no sanitary powers, and prior to the Revolution there seems to have been no sanitary legislation worth mentioning in the whole State. Even down to 1804, all legislation affecting the public health, which related mostly to quarantine and the removal of nuisances, was limited in its application to the cities of New York, Hudson, and Albany, the only ones of note at that time in the State.

In 1820, an elaborate Act of forty-five sections provided for a Board of Health for the three cities just named, and the navigable waters connecting them. It included a provision for Health Wardens to inspect dwellings and other buildings. After the cholera epidemic of 1832, local health boards were formed throughout the State. At about 1850 the Common Councils of New York and Brooklyn were each constituted Boards of Health, with the result of so mixing up politics with health administration that in 1873 a change was made, and the present Board of Health was created. The powers of the present Board of Health, as regards buildings in New York, are thus set forth in the Sanitary Code:—

The first provision, sect. 17, is sufficiently comprehensive:—'No person shall hereafter erect, or cause to be erected, or converted to a new purpose by alteration, any building or structure which, or any part of which, shall be inadequate or defective in respect to strength, ventilation, light, sewerage, or of any other usual, proper, or necessary provision or precaution, nor shall the builder, lessee, tenant, or occupant of any such, or of any other building or structure (within the right or ability of either to remedy or prevent the same), cause or allow any matter or thing to be done in or about any such building or structure dangerous or prejudicial to life or health.'

Sects. 18 and 19 repeat much of the above, and add that no cellars or any apartment not at least two feet above the level of the sidewalk are to be used for sleeping purposes, or as a place of residence, nor any apartment where the floor is damp, or which is impregnated with unwholesome odours. Overcrowding is forbidden. 'Adequate privies or water-closets' must be provided and kept in a cleanly condition. Rooms shall be 'adequately lighted and ventilated.'

* Abridged from the *Medico-Legal Journal*, New York.

Later provisions (Sects. 190-93), adopted 1877, required that in hotels, lodging, and tenement houses proper traps shall be provided under all plumbing fixtures, and insist on the ventilation of privy vaults and the extension of soil-pipes through and above the roof of every dwelling.

Sect. 201, adopted 1879, requires a permit for lodging-houses. In short, the powers of the health authorities, so far as the law is concerned, are absolute, and justified the saying that the Shah of Persia intended to establish a similar board in his dominions, in order to increase his power over his subjects. 'Its control over nuisances,' says Dr. Stephen Smith, 'extends from the suppression of a crowing cock, which disturbs the morning slumbers of the sick, to the removal of the gigantic corporation of butchers, numbering 250 establishments.'

But many of the provisions of the Code are vague and too general. The language is not specific, and leaves it to be disputed as to what is 'adequate ventilation and light,' and as to what are unwholesome odours and exhalations. If strictly enforced to the letter the Sanitary Code would revolutionise the metropolis, but it would be impracticable to do this and also impolitic. The Tenement House Act of 1867 was the first law passed directly relating to sanitary building in New York City. Its main provisions were:—

1. The requiring in every interior sleeping-room of two ventilating or transom windows, each having an area of three square feet, and communicating either with a hall or with a room opening on the external air.
2. A suitable ventilator on the roof over the hall stairway.
3. Fire escapes to be provided.
4. A water-closet or privy for every twenty occupants, and connected with the street sewer when such exists.
5. Cellars not to be used as dwellings without a special permit.
6. Garbage to be removed, and tenements to be kept clean and whitewashed twice a year.
7. Owners' and agents' names to be posted on the front of the building.

This has been a dead letter. These provisions enabled the health authorities to effect many reforms; but they were lacking in several particulars, afterwards supplied in subsequent amendments.

In the autumn of 1876 general attention was drawn to the evils of the New York tenement house system by several circumstances. Special investigations had been made by two leading charitable associations in the city into the condition of this class of buildings, and important facts relative to their defects made public in reports and through the press. In December of the same year the sanitary engineer offered 500 dollars in premiums for the best designs for a model tenement house on an ordinary city lot, 25 x 100. In response to this competition 206 designs were sent in by architects from all over the country, and were exhibited. While the plans selected for approval came nearest to fulfilling the terms of the competition, the committee emphatically declared that in their view it was impossible to secure the requirements of physical and moral health within the narrow and arbitrary limits of the ordinary city lot; they, therefore, recommended further agitation to secure needed legislation, regulating the number of occupants, the amount of open space, the provisions for light, ventilation, and cleanliness on sound sanitary principles.

Simultaneously with this announcement a mass meeting was held, at which a committee of nine was nominated to suggest measures for reforming

the tenements. Messrs. D. Willis James, W. Bayard Cutting, W. W. Astor, Cornelius Vanderbilt, R. T. Auchmuty, James Gallatin, Henry E. Pellew, F. D. Tappen, and C. P. Daly, who composed this committee, immediately proceeded to take steps toward the formation of a joint stock corporation for the erection of a block of model houses for working men; and also drafted a Bill (with the aid of Judge Charles P. Daly and of Professor Chandler) amending the existing Tenement House Act, which passed the Legislature in May. A very desirable clause, imposing a licence on all tenement houses, was unfortunately struck out, and a clause inserted instead appropriating 10,000 dollars to aid in enforcing the law.

The Tenement House Act of 1867 did not prevent a building covering the whole lot. This was remedied by requiring a clear open space, of not less than ten feet, between the building and the rear line of the lot, and by authorising the Board of Health to restrict the proportion of lot to be covered to 65 per cent., whenever they deemed it advisable, except in the case of corner lots.

The amended Act requires that every sleeping-room 'shall have at least one window, with a movable sash, having an opening of not less than twelve square feet, admitting light and air directly from the public street or yard of the said house, unless sufficient light and ventilation shall be otherwise provided, in a manner and on a plan approved by the Board of Health.' The Board are now approving plans where the inside rooms open upon shafts of the following dimensions: For houses not more than three storeys in height, twelve square feet; not more than four storeys, sixteen square feet; not more than five storeys, twenty square feet.

Nothing was said about overcrowding. The Board are now authorised to require an owner to reduce the number of occupants of any tenement house that they consider to be overcrowded, until a minimum of 600 cubic feet of air space is secured to each tenant. The amended law also permits the Board of Health to require the presence of a responsible person, either the owner or a janitor or house-keeper, in every tenement house occupied by more than ten families. For a number of years the Board of Health had been very much assisted in their work by the co-operation of the sanitary company of police. In 1876 they were deprived of their services, and the committee found that the department was much crippled in its usefulness thereby. A provision was incorporated into the new law, which has secured to the Board the services of thirty policemen.

On March 12, 1883, a law was passed by the State Legislature prohibiting the making of cigars in tenement houses after Oct. 1. The chief objections to the tenement-house cigar-factories are that they are a sanitary nuisance, detrimental to education and an illegitimate interference with a legitimate trade. The mortality among children is excessive, as it must be when children, from six years of age upward, spend most of their time stripping tobacco and bunch-making. The school laws cannot be enforced, and the parents receive such low wages that they are compelled to make their children work. These places are also physically demoralising, owing to bad ventilation, long hours of labour, the night and Sunday work, and eating food that is impregnated with tobacco. There are from 18,000 to 20,000 persons engaged in cigar-making in the

d factories in New York, and there are 300 manufacturers. The tenement-house owners number 28, and they employ from 3,750 persons. The hours of labour in the are from 50 to 57 per week. In the tenements they vary from 70 to 100 hours per week. The workers get from 1½ dols. to 2 dols. and less than is paid in the factories. In their long hours they can make cigars in they are consumed, and that is why so far-makers are out of work in this city. Physicians have strongly condemned this. They say that bronchial catarrh, pneumonia, inflammation of the lungs, and various nervous diseases are engendered in houses where such a crowded life is carried on.

A prohibition may be necessary in time with the manufacture of clothing in tenement houses, under special restrictions, owing to the contagious disease being conveyed by the contact of the public at large.

Following winter the same public-spirited man who had obtained the amendments to the Tenement House Act secured the adoption of a law requiring that the plans of the plumbing and drainage of all new buildings must be submitted to the Board of Health for approval, and that they shall be executed in conformity to the regulations and subject to official inspection. It was decided that all plumbers should be registered and licensed by the Board of Health and licensed. The value of the law is demonstrated almost daily, and the fact that the provisions are being adopted by other cities in the country, and are recommended for adoption, is the best proof of its merits. It prevents, that all plumbing in new buildings be executed according to certain rules; these have been drawn up in consultation with engineers, and sanitarians of the highest standing, and hence represent the best thought and practice of our time in this line of work. They insist on the use of good material and workmanlike work accessible and as far as possible new, thorough ventilation and perfect traps, disconnection of all house drains from sewer or cesspool, separation of the water supply from any source of pollution, abundance, isolation of fixtures from living rooms, and, finally, suitable tests when the work is done to see that the plumbing is safe. As a result we have had all the new houses plumbed since they went into operation are free from defects common to the mass of other dwellings, and which have seriously affected the health of their occupants. The most ardent opponents of the law have ceased to make complaints against it. The manner of its enactment is a credit to the health authorities, while the success is due to Messrs. Gallatin, Meyer, and Lindler, who secured the passage of the law. In the first eight months of 1882, dwellings to the value of 3½ million dollars were erected in the city. What is now needed is to extend the scope of this law so as to include alterations in old buildings as well as new ones, more especially large jobs of work costing over 100 dollars. Registration of plumbers should also be supplemented by a formal examination before a competent authority each applicant for registration, so that they may be able to distinguish between competent and incompetent workmen. At present the registrars are in no form, and all applicants stand on the

same footing. If, however, they had to prove their qualifications by such an examination as I have suggested, the best plumbers would receive the credit they deserve, and the ignoramus would have to be content to wait longer for a certificate or receive one of a second grade.

Within a few years the attention of the public has been drawn to the very high buildings, mostly for offices or apartment houses, being constructed in all parts of the city, and their effect upon the health and safety of their inmates and persons living near by. This is a subject which calls for immediate attention, and a committee of leading citizens are now considering what restrictions should be placed on the height of such buildings. The chief objections to the lofty buildings now coming into vogue is that they darken the streets and exclude sunlight from neighbouring windows. The right to light and air has been established by innumerable lawsuits in England, and is not to be disputed. By general consent, the property adjoining a huge French flat is lessened one-fifth or more in value by the erection of the latter. The adjacent streets and yards are made permanently damp, lower rooms become uninhabitable, neighbouring chimneys and soil-pipes have to be raised to be of any service, the wind sweeps through the narrow streets with gusty violence, causing discomfort and sore throats; lastly, tall buildings invite fire and threaten the safety of their inmates; they also disfigure the appearance of the city, and may spoil a whole neighbourhood, as they are rarely tastefully designed. An example of this is seen on Fifty-seventh Street, which contains some of the finest residences in the city, whose architectural appearance is wholly destroyed by several huge structures built in the plainest and cheapest manner, which inevitably seize the visitor's eye and mar all their exquisite surroundings. It is quite time a stop was put to this practice, and that all buildings, or, at least, dwelling-houses, should be limited in their height as in Paris, proportionate to the width of the street, avenue, or open space in front.

FEVER FROM WANT OF WATER.—At the last meeting of the Hexham Rural Sanitary Authority, Dr. MacLagan, Medical Officer of Health stated that several fresh cases of typhoid fever had broken out at Eltringham; in his opinion the outbreak of the disease was entirely caused by deficiency of water. The Inspector reported that he had supplied disinfectants to eleven fever-infected houses in the small village of Eltringham.

PUBLIC BATHS AND WASHHOUSES.—At a meeting of the parishioners of St. Bride, Fleet Street held in the vestry of the church, under the presidency of the vicar, the Rev. E. C. Hawkins, M.A., the question of the erection of public baths and washhouses for the parish was brought under consideration. Mr. J. Lewis moved a resolution affirming the necessity for some such provision, and suggesting as a site the disused burial-ground near the Farringdon Street fruit market. He said the parish had in hand the sum of 3,000*l.*, in the shape of an accumulated fund from parochial property, and he thought the money could not be better used than in providing an establishment of cleanliness and health. The vicar, in putting the resolution from the chair, expressed his warm approval of the project, and said that the money derived from parish property would be far better spent in establishing an institution for the public good than in distributing it in doles to a few individuals, the inevitable tendency of which was to reduce wages and raise rents. The resolution was adopted unanimously.

THE REGISTRAR-GENERAL'S ANNUAL REPORT.

By J. HAMPDEN SHOVELLER.

THE Forty-fifth Annual Report of the Registrar-General of England has been recently issued. It contains detailed abstracts of the marriages, births, and deaths registered in England and Wales during the year 1882, prefaced by a valuable and interesting analysis of the vital statistics of that year.

The growth of the population of England and Wales during 1882, occasioned by the excess of births over deaths, was 372,360; but this does not represent the real increase. Emigration and immigration have to be taken into account. The population of this country in the middle of 1882 is estimated at 26,413,861, an increase over that of the preceding year of 352,125, a number more than 20,000 less than the balance between the births and deaths of the year. In consequence of the unprecedentedly large numbers of emigrants during the past few years, the loss of population due to the large excess of emigration over immigration must recently have been considerable.

The marriages during 1882 numbered 204,405, equal to a rate of 15.5 persons married to each 1,000 persons living. It is satisfactory to note that the marriage-rate, which fell year by year from 1873 to 1879, has since steadily recovered. Of the marriages during 1882, nearly 72 per cent. were solemnised according to the rites of the Church of England. The marriages included those of 124 persons described as divorced. In no less than 15 per cent. of the marriages the officiating minister neglected to insert in the register the name of both parties, or of one or other of them. The mean age at marriage among those whose ages were duly stated was 27.9 for males and 25.6 for females. The educational test supplied by the signing of the marriage register with a mark instead of the person's name shows a progressive improvement, though it has not, during the last few years, been so rapid. The proportion of persons who were unable to sign their names was 15.2 per cent. in 1882, which was a smaller proportion than in any previous year; still the fact remains that even now 15.2 per cent. of the men and 17.1 per cent. of the women of England are unable to sign their names in writing; though in the year 1850 no less than 31 in each 100 men and 46 in each 100 women who married were unable to sign the marriage register.

The total number of births registered in England and Wales during the year 1882 was 889,014, equal to a rate of 33.7 per 1,000 persons estimated to be living. This was the lowest birth-rate recorded since 1853, and was considerably below the average rate in the preceding ten years. Of the 889,014 births, 452,752 were males and 436,262 females, so that to each 100 females 103.8 males were born. The proportion of illegitimate births was fewer in proportion to the population than in any previous year; though, in consequence of the diminution of the legitimate births, resulting from the decline in the marriage-rate, the proportion of illegitimate to total births did not show any decline.

The deaths registered in 1882 were 516,654, and were equal to a rate of 19.6 per 1,000 persons living. With the single exception of 1881, when the death-rate was 18.9, the death-rate in 1882 was the lowest on record. During the ten years 1871-80 the rate

averaged 21.4, and had the death-rate in 1882 corresponded with this average, no less than 48,338 more deaths would have been registered. This improvement in the general health of the country appears to have been shared in by persons at each age-period during each of the two years 1881 and 1882, so that the conditions prevailing in those years must have been favourable to health in all stages of life. The rate of mortality among infants showed the usual excess in the manufacturing and mining counties, and was lowest in the agricultural counties.

In the urban population of England and Wales, consisting of about fifteen millions of persons, the death-rate during the year under review was 21.1, while it did not exceed 17.2 in the rural population of about ten and a half millions. Both these rates showed a marked decline from the average rates in preceding years.

The number of names added to the alphabetical indexes of marriages, births, and deaths in England and Wales during 1882 was 1,814,478. These records, for the convenience of public reference, extend from the year 1837, when civil registration was first established, to the present time, and contain an aggregate number of 66,619,375 names. The number of searches in these records during 1882 was as many as 33,597.

POISONOUS DYES.—The danger of wearing next the skin articles of clothing dyed with substances obtained from benzol and other products of coal tar has been fully recognised by medical men, who have given instances of the ill-effects caused through the absorption by the skin of these irritating and poisonous compounds. Their warnings are repeated and illustrated in a case of exhibits sent to the Health Exhibition by an authority on skin diseases, Mr. James Startin, M.K.C.S. In this case, which will be found in the Dress Section in the East Quadrant, near the entrance from the conservatory, are specimens of some of the beautiful aniline colours—rosaline, magenta, violet red, methyl violet, Bismarck violet, &c.—and gloves and stockings dyed with the substances by which these hues are obtained that, in cases coming under the treatment of the exhibitor, had produced eruptions on the skin of women and children, in some instances of a very severe character. Below are shown many vegetable dye stuffs, and gloves, stockings, and other portions of dress dyed with them, from which no danger of the kind need be apprehended.

VEGETARIANS are taking up the feeding of the children of the poor on a self-supporting basis. A correspondent describes the experiment in the *Daily News*. A room which had a small fireplace with hobs was taken in King's Cross court at 3s. a week; three saucepans and other cheap utensils were bought; two or three mothers were asked in to help and to learn to cook; a shilling was invested in lentils and vegetables, and 6d. in two whole meal loaves. So the dinner was made by the teacher and the mothers, and eaten with relish by the mothers and some fifteen to eighteen children for a week. So far the dinners were free. The mothers were then asked to contribute; they were to take the cooking in turn, day by day; one fire was enough; and the cost had been found to vary from 8d. to 1s. for twelve to eighteen portions of little more than a large breakfast cup each. Accordingly the women are now cooking daily at their own expense the two-gallon saucepan full either of strong lentil soup, peas pudding, or sweet porridge. They feed their own children—each woman has three or four—and they have some left, which others in the court buy at three ladles for a penny. One day they fed their party for a shilling and sold the remainder to a non-co-operator for 2½d.; as 'the soup is beautiful.'

ERATIONS IN THE UNITED STATES, AND HOW THEY ARE MET.

AMERICAN PLUMBING LAWS ARE CARRIED OUT.

(FROM OUR AMERICAN CORRESPONDENT.)

the States, so far as I know, which pretend to at all on this subject, the power to enforce is placed in the hands of the boards of The United States Legislature, or the State make the laws; and it is the duty of the health boards in the various cities to see they are properly carried out.

A few New York laws went into effect three years ago. The State Board of Health, as soon as possible, began to prosecute certain dealers in groceries for violating provisions in the law, and this was merely the beginning of an campaign against injurious and dishonest dealers.

To get a fair idea of how these laws are enforced, I summarise here, very briefly, some of the prosecutions and prosecutions carried on by the New York Board of Health. Teas were found to be adulterated with mineral substances, and were, therefore, condemned under the section of the State Law which prohibits their sale 'if coloured, or coated, or oiled, or powdered, whereby damage is done or made to appear better than they really are of greater value.' Such action in a community of the importance of New York is of great moment, and it arrests all unsound dealers, as soon as they reach this country, they are scattered through the southern and northern States, where laws are less strict, and where, consequently, the harm done by such goods would go unchecked. Teas I speak of especially those which are shipped to America by English dealers and palmed off on our unsuspecting poor, who are captivated by the low price at which they

have any practical results followed these prosecutions in New York? The continuation of many will, I think, answer this question satisfactorily.

Over a thousand packages of Pingsuey teas were seized by the Custom House officials, and after this 270 additional packages were seized and shipped to London. These were intended to be sent to the coal regions of Pennsylvania. In the first ten months after the passage of the New York law, the port of New York rejected 3,000 lbs. of drugs, and to present date has rejected over 900,000 lbs. of adulterated drugs and teas.

Loaves of wheaten flour and bread were found adulterated with alum, which, when mixed with partially decomposed bread, makes it look

Vinegars were found to be of an inferior but free from harmful adulterations. Spices largely mixed with other substances, though poisonous adulterations have been discovered.

Candy is especially out of favour with the people as is no more than natural when it is found that chromate of lead is an important constituent. In medicines, quinine pills are found to be below the standard fixed by the law. Dealers in these articles are being tried to-day for violating the law of the land; and importers are

being punished by having their goods sent back to the shipping point.

In some of the States special legislation has been accomplished concerning the adulteration of milk. The Rhode Island law prohibits the sale, or the exchanging, of adulterated milk. All milk must contain $2\frac{1}{2}$ per cent. of milk fats, unless the dealer is willing to mark distinctly upon each can the words *skimmed milk*: such milk is only to be sold out of a can so marked. If milk be shown upon analysis to contain more than 88 per cent. of watery fluids, or to contain less than 12 per cent. of milk solids, it is to be considered adulterated. A first conviction under this law results in a fine of 20 dollars, and, for every subsequent conviction, a fine of 20 dollars is imposed, with imprisonment for ten days.

Acting under the New York law, experts made a thorough examination of the dairy products of that State, and the adjoining commonwealths of Connecticut and New Jersey. It was found that the poorest milk sold was taken from the healthiest cows—milk which contained only 2.5 per cent. of solids and 88.5 per cent. of watery fluids. Skimming was considered to be very generally followed, houses having been erected for that special purpose. These experts discovered that butter was commonly adulterated with oleomargarine, lard, and cotton-seed oil; and, although these are not necessarily harmful, they have been condemned as fraudulent, as their specific gravity is lower than that of pure butter. In 1881, 800,000 lbs. of 'lard cheese' were manufactured in New York and sold for genuine cheese, which it closely resembles.

In Massachusetts the State Board of Health is vigorously prosecuting milk adulterators. The wholesale druggists have also suffered at the hands of this Board for selling drugs with a lower standard than that fixed by the 'Pharmacopœia.' Several firms were lately prosecuted in court, and escaped only by some legal technicalities. Let us hope, however, that they were sufficiently scared not to attempt fraudulent processes a second time. The New Jersey Board is likewise engaged, and has its analysts busily at work testing samples of food, milk, and drugs. Probably the laws against the adulterations of liquors are those least regarded in the United States. The following substances are condemned:—*Cocculus indicus*, vitriol, grains of paradise, opium, alum, capsicum, copperas, laurel water, logwood, Brazil wood, cochineal, sugar of lead, and other substances 'not necessary ingredients in the manufacture thereof.' The punishment is heavy, yet we rarely hear of its being carried out, and seldom read of prosecutions under this law. One or more of these injurious substances enter more or less into almost all of our liquors.

The inspectors of meats point out the danger arising from decomposition, and the consequent presence of trichinæ and other parasites. Our housewives know, however, that thorough cooking is the remedy for this evil, and that meat subjected to a temperature of 160° may be eaten with perfect safety. It must be confessed that the system of meat inspection in our large cities is unsatisfactory, as it provides for the examination of the article only after its arrival at the market. The animal should be examined before the killing, as disease is often manifest before death. A great deal of expense would thus be saved, to say nothing of the advantage accruing to health.

It must always be remembered that adulterators are

to be prosecuted—not necessarily for selling a harmful article, for their goods are frequently, generally indeed, quite harmless—but for practising fraud. This is the line taken by our Boards of Health. Oleomargarine, for example, has been proved to be pure, and its manufacture goes unchecked; but when oleomargarine is sold for butter, a fraud ensues, and the public suffers. The American people, as a mass, hate dishonesty, and will support all legitimate efforts to suppress it.

PLUMBING LAWS.

The Boston plumbing law seems to be regarded as a dead letter, and to remedy this state of affairs, efforts are being made to transfer its enforcement from the Building Department to the Board of Health. Without meaning to cast any reflections upon the Building Department, this must be conceded as a wise movement, for the Board of Health is obviously the proper authority in such matters. My next letter, I doubt not, will convey to the readers of the *SANITARY RECORD* the practical results flowing from this transfer if it is accomplished, as I think it will be.

Baltimore has joined her sister cities in putting forth stringent plumbing laws. The Inspector of Plumbing appointed under the Act is a man who understands his business, and in whom the plumbers have confidence. These latter have fallen into the new order of things, and I have not heard of any arrests. In this enlightened age the great mass of plumbers are very willing to support all proper legislation, for they recognise that it brings with it its own reward in the shape of the increased confidence of the public. It is the plumbers, indeed, who are generally the first to move for plumbing regulations. The Baltimore law is deficient in one particular. Although registration at the Health Department is required, there are no provisions for examination of candidates. The Health Commissioner is acting as well as he can under such a limitation, and all candidates are pressed for assurance that they will comply with the laws.

Reports come from San Francisco that the plumbing regulations there enacted are being carried out to the full letter. Cases are being tried in Court for failure to register, and the Supreme Court has been appealed to in one instance by a man who used common galvanised pipes for soil-pipes, without traps or means of ventilation.

MR. JAMES B. PETTER, of Yeovil, has issued a new catalogue of the *Nautilus Grates*, containing some new designs and clearly showing how these grates may be fixed in any fireplace.

FISH FOR THE WORKING CLASSES.—One of the results of the late Fisheries Exhibition has been the pushing of a new system of co-operation among working men, whereby they can, with the aid of their employers, obtain good wholesome fish for dinner at wholesale prices. The plan was introduced into Darwen some time ago, and has been lately tried at Messrs. Pilkington Bros. & Co.'s Park Place and Audley Range Mills at Blackburn. The hands were able to obtain skate, cod, fluke, and haddock at an average cost of 2½d. per lb., and halibut and turbot at 6d. It is supplied by Mr. R. Mills, of Grimsby. The trial proved so satisfactory that a second consignment of 4 cwt. has been obtained. There are about 450 work-people employed at the mills. The masters permit them to use the mill for the purpose of distributing the fish, and help beside in other ways.

CHOLERA.—HOW TO PREVENT IT.*

By SIR ROBERT RAWLINSON.

I HAVE lived through the prevalence of cholera in England in the years 1832, 1849, 1853, 1865, and in the Crimea 1855. Having visited and officially inspected seats of cholera at home and abroad, having also read up the literature of cholera and considered some of the theories advanced as to the causes of the disease, I wish at the outset to say that I have no theory of my own, and I fail to recognise in any theory sufficient fact to induce me to believe in speculations not based on established principles. Many of the reputed causes of cholera are ever present in crowded cities, towns, and villages—such as polluted subsoils, polluted water, putrid or semi-putrid meat, stale fish, unripe fruit, and intoxicating drinks; there are also foul cesspools, filthy and overcrowded tenements, and unspeakably dirty people—but no cholera.

When cholera rages as an epidemic it is in a sense arbitrary in only covering acres capable of being defined, and not spreading broadcast over continents. It, however, strikes crowded seaports, and travels along lines of greatest human intercourse; low sites seem to favour it, but elevation does not exclude it, as both yellow fever and cholera have prevailed occasionally at elevations up to 4,000 feet. Stratification is not answerable for cholera, as, if there are human beings living in sufficient numbers on granite, cholera may rage with as great virulence as on the tertiary. The first and prime element in a cholera epidemic is necessarily human life, which to generate the disease in its greatest intensity must be massed on swampy or low undrained sites, having been long occupied, unceasingly fouled, and densely crowded. Seaports, and the banks of rivers, may thus be said to breed cholera, but sewer and drain these sites, remove foul privies and cesspools, regulate the tenements, and at short intervals cleanse, ventilate, and limewash the slums, and cholera, if introduced, will not spread. Since the year 1848, the date of the first Public Health Act, very many millions sterling have been expended on main-sewering and house-draining, on establishing waterworks, and on streets improvements. I have had something to do with the movement, and must plead guilty to some of this expenditure. I have no reason to repudiate this class of works, but I do wish to exalt something much simpler and cheaper—namely, systematic and thorough scavenging, as, unless this is established and attended to, the sanitary engineers will to a considerable extent have worked in vain. The engineers must so sewer as to enable the entire abolition of cesspools and deposits to take place; to bring in an abundant and pure supply of water to be at constant service, and be taken by service-pipe and tap within the walls of every occupied house and single-room tenement. This, and this only deserves the name of a modern domestic water supply. There must also be closet accommodation and drains to remove soil and waste water. Do all this to the greatest perfection, and then establish and maintain unceasing scavenging, as on the full and proper execution of surface scavenging will depend the crowning results of modern sanitary measures. There must be no blackmail levying by dust-carts, nor sulking neglect if their tribute is not freely paid. There must be a water-van brigade, every water-van being specially

* Reprinted from the *Pall Mall Gazette*, July 2, 1884.

flush sewers and drains as required. lute and sole control of the waterworks e in the hands of the municipality, ater at prime cost may be used without ll sanitary purposes, as by hose and jet to urts, yards, and passages, pavements and equal to that effected now and then by a lower—this will be the ultimate aim of 3. All that water can remove must be way; all matter liable to become putrid consumed by fire. There must be no ge heaps of refuse stored and sorted to tions to be sold as manure, every pound tained for such manure having cost two rling or upwards to bring it to any avail- et. In Liverpool, Dublin, and some other vns this refuse either is or will be disposed er-barges into the sea: there can be no ny in retaining refuse liable to become offen- midst of populations waiting for a market. preceding remarks do not indicate in ee what may be done to prevent a spread the writer will have missed his mark and n foolishly. In anticipation of cholera on of Great Britain and Ireland, temporary tals—roomy and airy—may be erected in spaces; water-tanks on wheels—street , in fact—to take fresh water, may be eaps of foul refuse may be covered over lime, if near human dwellings, as to stir use to remove it under a blazing sun will e poking up a slumbering set of inflam- bustibles. Cleanse and wash crowded alleys; cleanse, ventilate, and lime-wash if necessary; all crowded tenements, ouse-to-house inspection, insist on instant e sick to hospitals, compel burial of the ort intervals, and disinfect clothing and If there are no means for public washing cting let such be established, as portable apparatus is an easy thing to purchase. should be done carefully and gratuitously r, when they will aid the local authorities. or be spoken to by ministers of religion ominations, let the measures taken to d disinfect be explained by popular o that local rioting and hospital wrecking ided. Teach by precept and example, and not removed, will be greatly weakened. : stated that ships in seaport towns should as temporary cholera hospitals, nor old any sort, such as several storied disused ; but put up large and airy temporary als, having abundant ridge ventilation, atients from direct draughts of air, clothe ly, and diet simply, water or milk being a final warning, I say, for the present, ols alone—that is, don't disturb them a of lessening the evil, but as far as pos- m off from house connections and dis-

the various Continental cities, with their spools, will be wise to let their 'sleeping dormant cesspools—alone at present, as will only add fuel to active fire. Their t be on removal to temporary hospitals try, and surface cleansing, fumigating, 3, and ventilation. In India the scavenger e officer are the right hand of the medical scavengers cleanse and burn all burnable ollice officer guards the supplies of water.

THE SANITARY RECORD.

JULY 15, 1884.

The Editor will be glad to receive, with a view to publication, announcements of meetings, reports of proceedings, and abstracts or originals of papers read before the members of any sanitary or kindred association.

THE NOTIFICATION OF INFECTIOUS DISEASES.

It has come to be almost a commonplace of sanitary literature to read that the question of the notification of infectious disease has entered upon a new phase—the said new phase usually being a declaration by some one or another person or committee supposed to speak with authority, that notification is, or is not, desirable and necessary for the protection of the public health. It is true that the crude notions that were at one time extant about notification and its uses are getting gradually discredited; and it has come now to be generally admitted that the mere sending in of a number of half-crown certificates to the local sanitary authority does not necessarily imply an immediate reduction of the death-rate from zymotic diseases. Notification is, in fact, only one precaution out of a large number of others, both dependent and independent of it, that need to be taken if infectious outbreaks are to be crushed in their infancy. Sanitarians of the more superficial order demand the compulsory notification of zymotic diseases as though it were an unfailing panacea for and preventative of epidemics. But the mere piling up of statistics is of no avail against the onward march of disease; and it is hardly worth while to ask for information unless it can be put to some useful purpose. As a complement to notification, powers of forcible entry by the sanitary officials and wider powers of removal to hospital are apparently needed if the fullest use is to be made of the information thus gained; and it is not difficult to foresee that this would involve very strained relations between the health officer and the medical attendant, as well as between the sanitary authority and the householder.

We have set out these considerations, certainly not from any antagonism to the principle of compulsory notification, of which, ever since the establishment of this journal, we have been consistent advocates, but because it has appeared to us that in the recent discussions on the subject notification has been regarded too much from the theoretical rather than from the practical view-point. Even in Sir Lyon Playfair's excellent remarks at the inauguration of the juries of the International Health Exhibition, 'disease registration' was spoken of in terms that seemed to invest with a wholly undue importance the weekly sheets of infectious sickness. It is precisely in proportion to the action which is taken upon these indications of disease that the success or failure of such a system rests. Death-rates are the only tests at present available of the efficacy of sanitary action, and probably our readers will need no caution that rigid conclusions cannot properly be drawn from death-rates.

Pending the Committee of Inquiry or Royal Commission that has been called for as to the working of the notification of infectious diseases in those towns where it is compulsory under local Acts, it has appeared to us useful to attempt as far as possible the testing of the principle in question by the statistical method—a method admittedly imperfect, but still the only one at present open to us. With this view, we have entered into correspondence with the health officers of the thirty-eight towns in which notification is compulsory, and have invited their co-operation in sending us each month a tabulated statement of the notified cases and deaths from certain specified diseases which have been registered in their boroughs. Of the results of this appeal we shall speak further on; but meanwhile it may be convenient to give the names of the thirty-eight towns which were more or less in the mouth of every speaker at the two separate discussions which took place on the subject last month in the Conference Room of the International Health Exhibition. The towns are:—

	Act of		Act of
Aberdeen	1881	Huddersfield	1880
Accrington	1882	Jarrow	1878
Barrow-in-Furness ..	1881	Lancaster	1880
Birkenhead	1881	Leicester	1879
Blackburn	1879	Llandudno	1879
Blackpool	1879	Macclesfield	1882
Bolton	1877	Manchester	1881
Bradford (Yorks) ..	1881	Newcastle	1882
Burnley	1883	Norwich	1879
Burton-on-Trent ..	1878	Nottingham	1878
Bury	1882	Oldham	1880
Chadderton	1882	Portsmouth	1883
Derby	1879	Preston	1880
Dundee	1882	Reading	1881
Edinburgh	1879	Rotherham	1879
Greenock	1877	Salford	1882
Halifax	1882	Stafford	1880
Hartlepool	1883	Stalybridge	1881
Heywood	1883	Warrington	1879

In the Diary for 1884 of the SANITARY AND MEDICAL RECORDS, an elaborate table was given showing the various systems of notification in force in each of these towns; and this table has served as the text for many of the recent references to the question. The Diary has been for some time out of print; and it would take up too much space to reprint the table in these columns. But it may be stated generally in all the thirty-eight towns but two, Aberdeen and Edinburgh, the *occupier* is bound to give notice to the sanitary authority in case no medical man is in attendance. In six towns he is exempted from notification if there is a medical man in attendance, but in thirty he has to notify in any event. At only one town—Greenock—is the doctor exempted from notifying cases. Notification by the *medical attendant* has to be made to the medical officer of health in twenty-three towns, and to the sanitary authority in eleven towns. The three towns that have adopted the method of the medical attendant handing a certificate of the nature of the disease to the occupier, who is responsible for its transmission to the sanitary authority, are Bradford, Norwich, and Nottingham. At Aberdeen and Edinburgh the medical attendant has the entire responsibility for giving the needful notification. The whole of the twelve more recent Acts (those passed in the sessions of 1882 and 1883) have been passed on the model adopted by the Select Committee of 1882, presided over by Mr. Sclater-Booth.

It was of course too much to hope that the officials of every one of these thirty-eight places would respond to our invitation to forward us particulars of their infectious sickness. No compiler

ever yet obtained a complete set of facts unless had at his back the enforcement of a penal non-compliance; and the SANITARY RECORD is yet in these relations with medical officers of health. It will be seen from the list given above that number of the towns have only recently obtained powers for compulsory notification; and the reason to believe that in some, at least, of these system has not yet got into working order. Others, again, particularly in watering-places, a taken notion prevails that the facts known to the sanitary department should be kept as secret as possible 'with the view of preventing any panic.' We cannot now stop to argue against this excessively narrow-minded view of the objects and purposes of notification; we only mention it as a factor in the impaction of the information vouchsafed to us. Satisfactory to be able to announce, however practically all the health officers who are trusted to their local authorities, and are untrammelled by less fetters forged by sanitary committees, have responded cordially to our request, several of speaking in warm terms of the usefulness of proposed tables. As it is thought better to work with the figures for the beginning of a half year, rather than with those for the first half of the first half, we shall not this month statistically the figures with which we have favoured, but shall content ourselves with a merest outline of the general outcome of returns.

As a rule, measles is not included among diseases to be notified. Judging, however, from death returns, there appears to be more of it than might be expected. Accrington had 4 last month, Bolton 4, Burnley 7, Dundee 10, Oldham 24, Salford 6, and Warrington 10. Edinburgh cases of measles are notified to the Medical Officer of Health, and here 131 cases so reported during the month of June, though two deaths were registered. At Reading measles is notified, sixteen cases being recorded last month.

Whooping-cough again is usually not included in notification returns, but it is notified at Aberdeen where 108 cases (with three deaths) were registered last month; 36 deaths from this disease also occurred at Edinburgh.

The effects of the recent hot weather on mortality from *diarrhœa* had apparently manifested themselves, for at none of the towns were the deaths unusually numerous.

Of the more serious zymotic diseases, *scarlatina* appears to be unduly prevalent, especially in the shire. At Aberdeen 19 cases were notified in June; at Bolton, 45 cases; at Bradford, Yorks, there were 31 cases and 3 deaths; at Burnley, 12 cases and 2 deaths; at Derby, 22 cases; at Dundee, 15 cases; at Edinburgh, 86 cases and 2 deaths; at Huddersfield, 11 cases; at Newcastle, 44 cases in June; at Oldham, 17 cases and 5 deaths; at Preston, 23 cases and 3 deaths; at Reading, 10 cases; and at Salford, 68 cases and 4 deaths.

Diphtheria was chiefly prevalent at Aberdeen where 8 cases occurred with 5 deaths; at Dundee, 10 cases and 2 deaths; and Edinburgh, 19 cases and 3 deaths.

Enteric fever was disproportionately prevalent at Bradford, 6 cases and 4 deaths; Burnley, 1 case and 2 deaths; Dundee, 10 cases and 2 deaths; Edinburgh, 46 cases and 4 deaths; Old

ases; Preston, 8 cases; Salford, 15 cases and 6 deaths.

Typhus fever appears in the returns of Aberdeen, 1 case; Bradford, 1 case and 1 death; Burnley, 1 case; Dundee, 1 death; Edinburgh, 4 cases; Jarrow, 1 case and 1 death; and Salford, 2 cases and 1 death.

THE LEGAL ASPECT OF CREMATION.

A FEW months ago the advocates of introducing the practice of cremation into this country had their hopes raised by the ruling of Mr. Justice Stephen, in the case of *Dr. Price*, that cremation, as a mode of sepulture, is not itself illegal, but that in order to make it a crime it must be conducted in such a manner as to offend against public decency or against some of the positive requirements of the law. The decision was followed by the introduction into the House of Commons of a Bill for regulating the practice and preventing its abuse; but many members of Parliament chose to regard it as a Bill for legalising a practice which they disliked (forgetting that it was already decided to be legal), and the Bill was defeated. Many persons, both supporters and opponents of the practice, considered that the rejection of the Bill left cremation without any legal regulations or restrictions; but the law courts have recently shown that this is not so.

During the last spring assizes two women, named Stephenson, were convicted before Mr. Justice Hawkins at Leeds, on a charge of preventing a coroner's inquest by burning the body on which it was to have been held. Their case came the other day under the consideration of the Court for Criminal Appeal, and that court unanimously held the conviction to be right. The judges ruled that 'it is an indictable misdemeanour at common law to prevent a coroner from holding an inquest where the coroner has jurisdiction to hold it; and that, if he has information given to him upon which he might reasonably determine to hold an inquest, even though that information were not well-founded, it was sufficient to give him jurisdiction. The object of holding an inquest is to ascertain what was the cause of death, and how the deceased came by his death; and if persons, having possession of a dead body upon which there are reasonable grounds for the coroner to hold an inquest, were to be at liberty to destroy it, and so prevent the inquest, the consequences would be most formidable, and it would undoubtedly tend to give impunity to murder by destroying those traces by which alone the murder could be detected.' Upon the above grounds the conviction was upheld, and it may now be taken as settled that it is illegal to burn or otherwise make away with a corpse, in cases where an inquest ought to be held or has been ordered. In other cases, if the burning is conducted in such a manner as not to cause a nuisance or offend against public decency, there is no rule of law to prevent this mode of disposing of a corpse being adopted. Those who choose to adopt it must, however, take upon themselves the risk of doing so. As the practice is not regulated by statute, but merely by the unwritten rules of the common law, it is difficult to know beforehand what may or may not be done. A great deal of popular prejudice on the subject undoubtedly exists; and those who conducted a cremation might not improbably find themselves in the position of having to answer a charge of misdemeanour. Whether they

would be convicted would depend not only on the circumstances of the case, but on the temper of the jury, which upon such a question might happen to be extremely unreasonable. Whichever way the verdict were given it would probably not be disturbed, and at present a man who, with the best possible motives, conducted a cremation, might find himself branded with a conviction as a criminal.

The result of the legal decisions which have been given, and which commend themselves to common sense, coupled with the illogical refusal of the House of Commons to touch the question at all, is that cremation is not prohibited by our law, but in this country it is not safe for anyone to attempt to carry it out.

DISUSED BURIAL GROUNDS AS BUILDING SITES.

A DECISION which was given recently before Mr. Hannay, one of the Metropolitan police magistrates, seems likely to unsettle the law as to what is a proper site for building. The decision was given on the hearing of certain summonses which were taken out against a builder named Chambers, in order to prevent his erecting buildings on a plot of ground which was formerly known as the Peel Grove burial ground. The ground was laid out many years ago by its then owner as a burial ground under the name of the North East London Cemetery, but appears never to have been consecrated. It was, however, very extensively used, and during the eleven years previous to the year 1855, when it was closed by an order in Council, it was estimated that 20,000 persons were buried there; the graves were crowded, and many of the coffins were within four feet of the surface. After it was closed for burial, the owner removed the headstones and levelled the ground; rubbish was subsequently shot there, and recently the defendant, who had become the freeholder, commenced to build in spite of the prohibition of the Metropolitan Board.

If the ground had been consecrated, it is settled law that nothing short of an Act of Parliament could have authorised its conversion to secular purposes. A railway company might, under Parliamentary powers, have taken possession of it, and obliterated all traces of its ever having been a cemetery, as has been done in the case of many London burial grounds, or the ground might have been turned by the parish into a public garden: but it would have been impossible to build upon it. As, however, there was no evidence of its consecration, the Board were obliged to rely on their ordinary powers. They relied upon a by-law, made in pursuance of the Metropolitan Buildings Act, 1878, which provides that 'No house, building, or other erection, shall be erected upon any site, or portion of any site, which shall have been filled up or covered with any material impregnated or mixed with any faecal, animal, or vegetable matter, or which shall have been filled up with dust, slop, or other refuse, or in, or upon which, any such matter or refuse shall have been deposited, unless and until such matter or refuse shall have been properly removed by excavation or otherwise from such site.' The Act provides by section 14 that 'the term foundation shall mean the space immediately beneath the footings of the wall;' and the by-law requires the foundations of the walls of every house or building to be 'formed of a bed of good concrete, not less than nine inches thick, and

projecting at least four inches on each side of the lowest course of footings of such walls.' The buildings complained of had been erected *above* the soil in which interments had taken place, and without removing or disturbing the human remains which were there. Concrete foundations had been placed for the support of the walls, but otherwise nothing had been done to render the houses safe or habitable as regards the soil on which they were erected.

Upon the above facts being proved, the magistrate dismissed the summonses, holding that the by-law above referred to was intended only to apply to cases where artificial rubbish, impregnated with injurious matter, had been employed for the foundations of houses and buildings (in which he was probably right); and that it did not apply to such a case as the one before him. We are glad to see that the Counsel for the Board announced his intention of appealing. The words of the Building Acts and of the by-laws made under them are wide, but not as clear as could be wished, and it is important that everyone should know whether the law gives power to prohibit building on such sites as that in question. If no such power exists, the interference of Parliament cannot be too soon invoked in order to remedy the deficiency. Some parts of London and of other large towns have, no doubt, in days gone by been erected upon disused burial grounds; and even now, when centuries have elapsed since the last interment took place, it is doubtful whether such sites are not a source of danger to the health of those who live on them. Now that we are alive to the importance of constructing and keeping healthy dwellings, it is clearly necessary that local authorities should have, and should use, the power to prohibit crowded burial grounds, which have only been closed in recent times, from being used as fitting sites for the erection of dwelling-houses.

NOTES OF THE MONTH.

DEFECTS IN MODEL DWELLINGS.

ATTENTION has been called by Captain Douglas Galton, the well-known sanitarian, in a letter to the *Times*, to the fact that the remedy sometimes adopted for the amelioration of the dwellings for the poorer classes is apt to become as bad as the disease, or, in other words, where miserable tenements are replaced by substantial buildings these latter may contain many defects from which the former were to a certain extent free. A case in point is instanced at the Health Exhibition, where a model is shown of a large block of buildings about to be erected by the Metropolitan Railway Company to replace those demolished by the construction of the Tower Hill Extension. The model and drawings show a lofty building of nine stories, between 80 feet and 90 feet high, built round a square; the square being divided transversely by a block of equal height, forming two spaces or wells, containing in each over 1,300 superficial feet, and to the bottom of which no sunlight could penetrate and no circulation of air would be possible. The Metropolitan Building Act is in a great measure responsible for the small areas to be left in such cases, as the space bears no proportion to the size of the building; and a block of this magnitude is not compelled to reserve an open space any larger than

is required for a comparatively humble tenement. This is obviously unjust, but landlords and builders as a rule take advantage of it to the full where their pockets are concerned. Sanitary precaution has perhaps in this particular instance allowed this evil to be somewhat exaggerated, as each of these wells has an inlet for fresh air by means of two large passage-ways on the ground floor, sufficient to give an upward draught if the air be circulating at all; and although it is distinctly advisable to obtain if possible a direct or thorough draught, the exigencies of the site do not always admit of this. And as regards the sunlight, we are for many months of the year debarred from a glimpse of it; and when we do obtain it, it is a question whether it is valued to the extent that it should be by any class. Be this as it may, when we remember the terrible places that these lofty and well-drained buildings replace, we are inclined to think that an improvement has been made, although not to the extent that is possible or to be desired; but there is no doubt that the remedy must be sought by obtaining more stringent powers to enforce the reservation of light-ing areas in proportion to the extent of the building.

WATER RATES.

DURING the past month the time of the Police Courts, or at any rate the newspaper reports of their proceedings, have not been so much occupied with questions as to water rates as for some time previously. Householders and water companies are apparently beginning to know their position, and it may be considered that in most instances the rates have now been pretty well adjusted in accordance with the decision in Dobbs's case. One gentleman, indeed, wrote to the papers to announce the fact that the Grand Junction Company had actually, under the threat of legal proceedings, refunded some over-payments which he had made during previous years. This good fortune is not, however, one which many ratepayers can expect to have. As a rule they will find that the money which they have once paid, cannot be recovered back, and if their water rates have been reduced, they had better be content with their gain in the future and not rush into litigation for the sake of recovering a few shillings' overcharge of past years. As we have pointed out before, the result of the decision of the House of Lords is not to cause a general reduction of water rates. In some cases, and notably in the case of small houses, the rates have been slightly reduced, and people to whom the payment of a few shillings, more or less, is a matter of importance, have profited by the declaration of their rights. But the companies have done what they could to revise their rates without loss to themselves, and so far seem to have been successful. At the half-yearly meeting of the Chelsea company, the chairman told the shareholders that there had been no reduction in their income, nor did he believe there would be. They had revised their assessments, and wherever there had been any uncertainty as to the proper amount, they had felt it prudent *for the time* to take probably less than they were entitled to. The result had been that in not one single instance had they had a case in the Police Courts. The above statement shows the position adopted by the companies. They are now in a position of antagonism to the public, but wish to avoid hostilities if possible. Wherever they see a chance of raising an assessment or charging

for extras, they will seize it. If the ratepayers wish to keep their water rates down, they must watch them carefully, and without rushing into litigation must be ready in case of any fresh encroachment to protect their rights. The attempt to make war on the companies by means of confiscatory legislation has failed, for this session at any rate, but the companies are desirous, and from their point of view properly so, of making good their position as far as possible. Both parties are now inclined to stand on their strict rights, and neither can expect any concession from the other.

THE MANUFACTURE OF SMALL-POX.

A REPORT has just reached us of one of those extraordinary cases of recklessness in spreading disease of the most loathsome type, which we are at a loss whether to attribute to ignorance, cupidity, or utter indifference to the due consequences of such indefensible conduct. Mabel Wilson, a cowkeeper and milk retailer, has been fined 40s. and costs at the Newcastle Police-court for an offence which should have entailed a reasonably long term of imprisonment with hard labour. It seems that the woman is the owner of a house, in one room of which she lives with her daughter. In this room, 12 feet by 10 feet in dimensions, where her daughter's child had been suffering from small-pox for six or seven weeks, Mabel Wilson kept her stores of milk, and, with the assistance of the mother of the afflicted child, sold it without compunction to whoever was unlucky enough to want any of it. Eventually a neighbour found the matter out, and expostulated with Wilson, telling her that she should report the case to the medical officer. She, however, simply stated that she had had the services of a very experienced man, the said very experienced man being a chemist from whom she had bought some physic, but who had never seen the child. The neighbourhood at last revolted. Mr. Armstrong, the Medical Officer of Health, visited the place and found that the child was suffering from small-pox. The woman was summoned before the magistrates at the instance of the Corporation, the summons stating that on March 11, 1884, the defendant, then being the occupier of a house used for a human habitation, at Factory Yard, Gallowgate, wherein a certain inmate named Jane Ann Kitchen was suffering from small-pox, unlawfully did not, so soon as she became aware of the existence of the infectious disease, forthwith give notice thereof to the medical officer of health at his office, contrary to section 40 of the Newcastle Improvement Act, October 1882. The magistrates could not inflict a more severe penalty than 40s. with costs; but is it possible to imagine a more effective and repulsive factory of small-pox?

POISONING FROM SALMON IN A BULGED TIN.

PARTICULARS of the two fatal cases of poisoning from tinned salmon, which occurred lately at Wolverhampton, will serve to enforce the warning the public has already received as to the risk of using food of this kind unless thoroughly assured of its soundness. It appears that Sarah Dewen (51), her son, Frederick William Dewen (20), a cabinet maker, and her daughter, Agnes Dewen (18), purchased a tin of salmon for 7½d., of which they all par-

took at supper on May 21, the younger woman eating but sparingly. The man was first taken ill, suffering from abdominal pain, vomiting, coldness of surface, &c., and died the next morning. Then his mother and sister were attacked in the same way; and the mother, in whom the symptoms were from the first the most severe, died on the 24th. A younger sister, who just tasted the salmon, thought it bitter, and ate none. The medical man called in was of opinion that the symptoms observed might be caused by some animal poison being absorbed and affecting the nervous system, though he knew of no poison which would produce precisely the same results. The inquest on the bodies of the deceased was adjourned to permit of an analysis being made of the contents of the stomachs, &c., the small quantity of salmon left in the tin, and a tin of salmon having the same brand and procured from the same shop. At the adjourned inquiry the coroner read the report of the borough analyst for Wolverhampton. The examination by chemical means of the contents of the nearly empty tin yielded no evidence of poison, but on some tame mice being fed with small portions, one died in five hours, and another in six hours and twenty-five minutes. An infusion of tea, partaken of at the fatal meal, and portions of bread and bacon, were examined and found free from poison. The analysis of the viscera of the deceased man and woman gave the same negative results. No recognised poison demonstrable by chemical tests was present. It was noticed that the tin had the appearance of having been bulged by pressure from within, which would indicate that the fish had undergone some decomposition before the opening of the tin. The coroner said that it would be well the public should know the danger of bulged tins, and only purchase those with the ends depressed, showing properly sustained exhaustion. It would be well that all tins should be examined by some competent person before being exposed for sale. There was no law on the subject, but it would be much to the interest of vendors that they should themselves make a careful examination of all such goods received; they were well able to form an opinion as to the soundness or otherwise of the contents. While the jury were considering their verdict the coroner asked after Agnes Dewen. She was stated to be better, but not quite recovered. The verdict was that both the deceased persons 'died from the effects of poison contained in the salmon tin, arising from decomposition.'

METROPOLITAN AND PROVINCIAL SANITARY PROGRESS.

DURING the recent debate in the House of Commons on the London Government Bill, Sir Charles Dilke pointed out the apparently small improvement in the health of London as compared with that of other large English towns. He stated that while the death-rate in the past ten years in nineteen of the largest English towns had declined as much as 5·1 per 1,000 persons living therein, the London death-rate during the same period had declined only 1·1 per 1,000. He quoted these figures as giving in his opinion a very fair test of the effect of the Government of London upon the health of London as compared with the improvement of the health of other large English towns since the passing of the Public Health Acts of 1872 and 1875. Taking the three

years 1870-71-72, and the three years 1880-81-82, it is found that the annual death-rate in the former period in London was 23·4 per 1,000, and in the latter period it was 21·4. In the large provincial towns the rates were 27·2 and 23·0 respectively. The London death-rate, therefore, showed a decline of 20, and the large towns of 4·2 per 1,000 during the ten years. It will, of course, be noticed at once that, notwithstanding the greater decline in the death-rate of the large provincial towns, the rate of mortality in London, which has not shown so rapid a decline, is still below it. It will probably take a much longer period than another ten years to reduce the death-rate in these provincial towns another 4·2 per 1,000. Some exception was taken by members present to the assumption of Sir Charles Dilke that the death-rates he quoted were a test of the relative sanitary conditions of the metropolis and of the large provincial towns; and he is reported to have stated that the test of the death-rate in London must be altogether fallacious, unless a correction were made by including all the deaths of London residents which occur outside Registration London. It is difficult to see how this would greatly affect the argument that Sir Charles Dilke urged, for the proportion of deaths that occur outside the metropolis of London residents has probably not varied materially in the space of ten years, and the necessary correction applied to each of the London death-rates would hardly alter the amount of the decline which has taken place. It can scarcely be doubted, however, that the health of London would show a further marked improvement by the simplification and centralisation of sanitary authority. The present system, under which there are, according to Sir Charles Dilke, no less than seventy authorities dealing with infectious diseases, seems eminently suited to hinder that general metropolitan co-operation, especially in cases of epidemics, which alone can secure the success of efforts in the direction of further sanitary progress in the metropolis.

THE ADULTERATION OF FOOD AND DRUGS.

AN attempt has been made by the Local Government Board to secure a more general adoption of the Food and Drugs Act. In many districts, including large and populous cities, this useful measure is practically inoperative, while in others it receives but scant recognition from the local authorities. And perhaps but little progress can be expected until the constitution of these bodies is materially altered, for with a large proportion of small shopkeepers ruling their counsels it is hopeless to expect any radical improvement. It has often been pointed out that the Act of 1875 protects alike the buyer and the seller, and the central board, in issuing a circular letter to almost every sanitary authority in the country, has indirectly again drawn attention to this provision. The chief object of the letter is, however, to point out that 'any medical officer of health, inspector of nuisances, or inspector of weights and measures, or any inspector of a market, or any police constable under the direction and at the cost of the local authority appointing such officer, inspector, or constable, or charged with the execution of this Act,' may procure any sample of food or drugs, and if he suspect the same to have been sold contrary to the Act, shall submit the same for analysis. The task of collecting samples is one specifically laid upon inspectors

of nuisances by the Board's General Order of March 1880 prescribing the duties; but it rests entirely with the local authority whether or not they will instruct their officer to this effect. The circular is accompanied with extracts setting out the salient features of the Act, together with some useful instructions. A notable instance of the manner in which some local authorities carry out their important duties in this respect has recently occurred at Newington. In this district the Act has remained a dead letter, notwithstanding that the Local Government Board have made several efforts to bring about a better state of things. At a meeting of the Vestry, held a week or so ago, a member, in an outspoken speech, proposed that an inspector be appointed to carry out the provisions of the Act. He showed that at present a tradesman living on one side of a road could sell an adulterated article for which on the other side he would be prosecuted. He contended that this was a reproach to the local authorities of Newington, and should no longer be permitted to exist. This was followed by a discussion which reflected but little credit upon the majority of the members, who finally negatived the motion by a majority of 29 to 13.

UNCERTIFIED DEATHS.

DR. MACLAGAN, who has long complained of the imperfect and unreliable system of death registration carried out at Hexham, again calls attention in his last report to the lax manner in which investigations into the 'causes of uncertified deaths are conducted. Of thirty-eight deaths so returned in 1883, some were returned as the verdict of an inquest; some, as dictated by the coroner, from 'information received,' without any inquest having been held; and others were not certified at all. Even in cases where inquests have been held, frequently no medical evidence has been given. Dr. MacLagan thinks that were all cases of sudden death, or of deaths resulting from accident, or the subjects of suspicion, investigated by the health-officer, few of the causes of such deaths would remain undetected; but, unfortunately, no such cases came to his knowledge, except through the death register, and that frequently many days after the occurrence. Apart from this, it seems of the first importance that in all cases of suspicious death, and more especially amongst infants, the circumstances should receive a careful sifting at the hands of the coroner. The fear of publicity which attends these inquiries is known to exercise a wholesome effect on the minds of parents, and it might be well if the practice of holding them was adopted pretty extensively at Hexham.

CUTTING OFF WATER SUPPLIES.

It is much to be deplored that the Bill introduced by the Earl of Camperdown for the better regulation of the powers of metropolitan water companies should have fallen through, because the standing orders of the House of Lords had not been complied with. The Bill proposed that 'from and after the passing of this Act no supply of water shall be cut off unless the company shall have obtained an order granted on a summons to show cause why the supply of water shall not be cut off, and the order shall state when the cutting off may take place, as well as the reason for putting the power in force.' It is about this time of the year that the arbitrary and

often unjust manner in which the existing companies proceed to deprive houses of their water-supply becomes severely felt. In many cases it happens that the fault lies not with the tenant, but with the non-resident landlord. Thus, as Dr. Bristowe observes in a recent report on the circumstances of the poor in his district, not only are dwellings left for weeks without one of the first necessities of life, owing, it may be, to no default of the tenant, but the company coolly give the sanitary authority intimation of their proceedings, so that the vestry (acting in the interests of health) may take legal measures to compel landlords to have the water supply reinstated, and thus act as the company's cat's-paw. This practice obtains in almost every metropolitan and suburban district, and at Tottenham it is carried out very extensively. In the majority of instances the houses which are treated in this manner are occupied by the poorer class of people, who are not over-scrupulous in their habits. There is general uncleanness, and the lack of water leads to imperfect removal of excreta and consequent contamination of the air. As Dr. Watson, the local health officer, remarks: It is not difficult to see how an epidemic would spread with rapidity amongst the inhabitants of such houses, and it is fortunate that the illness which recently prevailed there was measles, and not one of the more dangerous and fatal of the zymotic diseases.

THE STATISTICAL WORKS OF DR. FARR.

It has long been the source of much regret amongst students of vital statistics, as well as among those practically interested in this branch of sanitary science, that the valuable statistical work of the late Dr. Farr is, from the form and manner of its publication, not generally available. The Sanitary Institute of Great Britain propose, in these circumstances, to publish a selection from Dr. Farr's official reports, papers, and addresses, and have confided the selection and editing of this memorial of his labours to the capable hands of Mr. Noel A. Humphreys, of the Registrar-General's Office. It is proposed that the volume should consist of not less than 450 pages 8vo., and that it be published at the price of 30s., or, to subscribers, one guinea, provided that the number of subscribers warrants the Institute in incurring the expense of publication. Intending subscribers are requested, therefore, to send in their names without delay to the Secretary of the Institute, in order that this Council may be able to determine whether they will obtain sufficient support to justify them in publishing the book.

PRECAUTIONS AGAINST CHOLERA IN THE TYNE.

At the last meeting of the Newcastle City Council Alderman Wilson, Chairman of the Tyne Port Sanitary Authority, stated it would be satisfactory to the inhabitants of both banks of the River Tyne to learn that the most vigilant precautions were adopted at the present time to prevent the importation of infectious disease from abroad. They had two inspectors who boarded every vessel that arrived in the Tyne from abroad, and, in addition to that, the Local Government Board had sent down a special inspector to assist in that duty. He trusted that this statement might allay any apprehensions that might be felt on the matter.

DISINFECTION AND CHOLERA IN PARIS.

ACCORDING to a Paris correspondent, writing to the *Times* on July 3, 'since Tuesday last a system of disinfection has been in operation at the Lyons Station, in Paris, for all passengers arriving there from Toulon and Marseilles or other infected places. Special carriages are reserved for such passengers and their luggage. On arrival in Paris the former are conducted into a waiting-room, the interior surface of which is covered with sawdust impregnated with lime and salts of copper. In this waiting-room there are vases containing a mixture which gives off enough nitrous acid to effect disinfection without impeding respiration. The passengers pass half an hour in this place. Meanwhile the luggage is conveyed to another room, opened, and the contents spread out. The room is then closed, and everything is submitted for a quarter of an hour to intense nitrous vapour. This measure is enforced by virtue of an order of the Prefect of Police, which has been issued pursuant to a law of 1790 and to an order of the Consuls of the 12th Messidor, year VIII.'

What useful purpose this mode of disinfecting may serve, unless to allay the fears of nervous persons, we do not know, and having regard to the nature of the disease, we do not see the value of the application of intense nitrous vapour to the respiratory mucous membrane. It may, moreover, be attended with no little danger to persons who had been wintering abroad on account of weak lungs. It would, we think, be more useful to examine the clothing of the passengers, particularly their underclothing, and in certain circumstances to see that these were destroyed and the passengers previously bathed and supplied with new clothing, or previously sent to a hospital, where they might be under medical supervision. We would suggest that all persons arriving in Paris from cholera districts be medically examined, that such as are not in a satisfactory state of health be placed under medical supervision, that such as may be suffering from diarrhoea be sent to hospital and their clothing destroyed, and that the names and addresses of those who appear to be in good health be sent to the sanitary authority of their respective places of abode, so that, in the event of their becoming subjects of diarrhoea, they might be promptly dealt with.

DR. BROUARDEL, member of the Academy of Medicine and professor of Medical Jurisprudence at the Paris Faculty of Medicine, has been elected to replace the late Professor Wurts as president of the Comité Consultatif of Public Health.

THE NATIONAL HEALTH SOCIETY'S PUBLICATIONS.—We spoke last month of an excellent little pamphlet about vaccination, which the National Health Society was suggesting for house-to-house distribution in the metropolis by the officers of the several Boards of Guardians. We are glad to find that the pamphlet has since been virtually adopted by the Local Government Board, who have officially recommended its circulation in a letter which they have addressed to the Metropolitan Guardians on the subject of the present epidemic of small-pox. Many thousands of copies of the pamphlet—not far short of 150,000 in fact—have been distributed during the last few weeks, and the demand still continues. Encouraged by this success, and always with the view of doing useful public work, the society has prepared a similar leaflet about cholera, the issue of which may be expected immediately.

THE PUBLIC HEALTH DURING JUNE 1884.

THE mean temperature at the Royal Observatory, Greenwich, during the month of June was $58^{\circ}0$; it was below the average June temperature in one hundred years, and was $1^{\circ}0$ below that recorded in the corresponding month of last year. An excess of temperature prevailed on ten days during the month, while on eighteen days it was below the average. The warmest day of the month was the 27th, when the mean was $66^{\circ}6$, and $4^{\circ}6$ above the average; the coolest day was the 6th, when the mean did not exceed $49^{\circ}5$, and was $8^{\circ}8$ below the average. Rain was measured at Greenwich on eight days during the month, to the aggregate amount of 2.2 inches, which exceeded by the fifth of an inch the average June rainfall in sixty-one years. During the first six months of this year the rainfall amounted to 8.9 inches, which was as much as 1.9 inches below the average rainfall in the same period of sixty-one years. The sun was above the horizon during 494.5 hours during June, but only 134.3 hours of bright sunshine were recorded at Greenwich; this amount was below the average of the corresponding month of the five preceding years 1879-83. The wind was very variable during the month, except from the 12th to the 22nd, when north-easterly winds prevailed.

In the twenty-eight large English towns dealt with by the Registrar-General in his Weekly Return, which have an estimated population of nearly eight millions and three-quarters, 23,243 births and 12,976 deaths were registered during the four weeks ending the 28th ult. The birth-rate, which had been 34.8 and 35.5 per 1,000 in the two preceding months, declined to 34.6 during June, and was slightly below that recorded in the corresponding month of either of the two previous years, 1882-83. The lowest birth-rates last month in these twenty-eight towns were 28.3 in Brighton, 29.2 in Halifax, and 30.2 in Huddersfield; the rates ranged upwards in the other towns to 40.2 in Nottingham, 40.5 in Cardiff, 44.2 in Preston, and 45.1 in Sunderland. In London the birth-rate last month was 33.1, while it averaged 35.8 per 1,000 in the twenty-seven provincial towns.

The annual death-rate in the twenty-eight towns, which had been 22.1 and 20.7 per 1,000 in the two preceding months, further declined to 19.3 during the four weeks of June, but slightly exceeded the rate recorded in these towns in the corresponding period of 1882 and 1883, when it was 19.0 and 19.1 per 1,000 respectively. The lowest rate of mortality last month in these towns was 12.9 in Brighton. The rates in the other towns, ranged in order from the lowest, were as follow:—Brighton, 12.9; Norwich, 14.9; Bristol, 15.3; Derby, 15.8; Leicester, 16.0; Hull, 16.3; Birkenhead, 17.2; Bradford, 17.4; Nottingham, 17.5; Salford, 18.1; Newcastle-upon-Tyne, 18.4; Sheffield, 18.6; London, 18.7; Birmingham, 18.7; Cardiff, 19.0; Huddersfield, 19.4; Plymouth, 20.1; Bolton, 20.5; Preston, 20.8; Blackburn, 21.4; Sunderland, 21.6; Leeds, 22.1; Halifax, 22.7; Manchester, 23.1; Oldham, 23.6; Wolverhampton, 23.8; and the highest rate during the month, 25.6 in Liverpool. While the death-rate in London during June, as above stated, was 18.7 per 1,000, it averaged 19.9 in the twenty-seven provincial towns. The 12,976 deaths from all causes in the twenty-eight towns during the four weeks of June included 2,026 which were referred to the principal zymotic diseases, of which 618 resulted from measles, 490 from whooping-cough, 250 from diarrhoeal diseases, 238 from scarlet fever, 180 from small-pox, 152 from 'fever' (principally enteric), and 98 from diphtheria. These 2,026 deaths were equal to 15.6 per cent. of the total deaths, and to an annual rate of 3.02 per 1,000. This zymotic rate showed a slight further decline from the rates in the two preceding months, but exceeded that recorded in the corresponding month of either of the two previous years. The death-rate in London during June from the principal

zymotic diseases was equal to 3.6, and exceeded by as much as 1.0 per 1,000 the average rate in the twenty-seven provincial towns, among which this zymotic rate ranged from 0.1 in Brighton, 0.3 in Derby, 1.1 in Bristol, and 1.3 in Hull, to 3.6 in London and in Cardiff, 3.8 in Oldham, 4.6 in Liverpool, and 4.7 in Wolverhampton. Measles caused the high zymotic death-rates in London, Oldham, and Wolverhampton, and scarlet fever in Cardiff.

Measles was the most fatal zymotic disease in the twenty-eight towns during June. The death-rate from this disease, which in the two preceding months had been 0.96 and 0.94, further declined to 0.92 during June, although it considerably exceeded the rate in the corresponding period of either 1882 or 1883. In London the rate of mortality from this disease was equal to 1.03 per 1,000, and showed a very slight decline from the high rate in the preceding month; in the provincial towns the measles death-rate averaged 0.83, but was equal to 1.89 in Liverpool, 2.12 in Blackburn, 2.55 in Oldham, and 3.99 in Wolverhampton. The rate of mortality from whooping-cough, which had been 1.10 and 0.96 per 1,000 in the two preceding months, further declined during June to 0.73, which, however, considerably exceeded the rate in the corresponding period of last year. The fatality of whooping-cough in London was again almost twice as great as in the provincial towns, among which it was excessive in Sunderland and Liverpool. The death-rate from diarrhoeal diseases was considerably below the average of corresponding months in recent years. The rate of mortality from scarlet fever, which had steadily declined in the seven preceding months from 0.84 to 0.40 per 1,000, further fell to 0.35 during June, and was lower than in any month on record. In London the scarlet fever death-rate was equal to 0.33, while it averaged 0.38 in the twenty-seven provincial towns, and was equal to 0.80 in Leeds, 1.30 in Sheffield, and 1.40 in Cardiff. The death-rate from 'fever' (principally enteric or typhoid) showed a slight increase upon the rate in the preceding month; the highest rates of mortality from this disease last month were 0.52 in Newcastle-upon-Tyne, 0.53 in Salford, and 0.98 in Portsmouth. The death-rate from diphtheria almost corresponded with the rates in recent months; the prevalence of this disease was almost entirely confined to London, Portsmouth, and Cardiff. During the four weeks of June 180 fatal cases of small-pox were registered in the twenty-eight towns; showing a considerable further increase upon the numbers in the four preceding months; of these, 137 occurred in London, 24 in Liverpool, 6 in Sheffield, 4 in Sunderland, 3 in Hull, 3 in Cardiff, 2 in Manchester, and 1 in Birmingham. Judged by the returns of the Metropolitan Asylum Hospitals, the prevalence of small-pox in London showed a further considerable increase during June. The number of small-pox patients under treatment in these hospitals, which in the eight preceding months had increased from 41 to 1,057, further rose to 1,290 at the end of June, and exceeded the number at any period since June 1881. The average weekly number of new patients admitted to these hospitals, which had been 52, 84, and 246 in the three previous months, further rose during June to 275.

The rate of infant mortality in the twenty-eight towns, measured by the proportion of deaths under one year of age to births registered, was equal to 126 per 1,000 during June, which differed but little from the rates recorded in the corresponding months of recent years. The rate of infant mortality in London was 126, and in the twenty-seven provincial towns it averaged 127, ranging from 57 in Brighton, 91 in Birkenhead, and 93 in Bristol, to 154 in Leeds, 161 in Liverpool, and 195 in Wolverhampton.

The death-rate from diseases of the respiratory organs, judged by the metropolitan returns, slightly exceeded the average during June. The weekly number of deaths referred to these diseases in London averaged 235, and the annual death-rate was equal to 3.1 per 1,000. In

Liverpool the annual rate of mortality from these diseases was last month equal to 5.1 per 1,000.

The causes of 312 of the 12,976 deaths registered in the twenty-eight towns during the four weeks of June were not certified, either by medical practitioners or by coroners. These uncertified deaths were equal to 2.4 per cent. of the total deaths, and corresponded with the rate in the preceding month. In London the proportion of uncertified deaths did not exceed 1.2 per cent., whereas in the twenty-seven provincial towns it averaged 3.4, and ranged from 0.9 and 1.0 in Brighton and Portsmouth, to 6.0 in Halifax, 6.3 in Sheffield, and 8.1 in Oldham.

Among the population living in the outer ring of suburban districts around London, estimated at rather more than a million persons, the annual death-rate during June from all causes was equal to 15.2 per 1,000, against 14.3 and 14.1 in the corresponding periods of 1882 and 1883. During the four weeks ending the 28th ult., 50 fatal cases of whooping-cough, 34 of measles, 22 of small-pox, 16 of scarlet fever, 16 of diphtheria, 14 of diarrhoea, and 8 of 'fever' were recorded in the outer ring. These 86 deaths were equal to an annual rate of 1.9 per 1,000, which was slightly below the rate recorded in the preceding month. The fatality of whooping-cough, measles, and diphtheria showed a decline. Measles, however, showed fatal prevalence in Edmonton and Bromley. The 22 deaths from small-pox registered in the outer ring included 16 in West Ham district (of which 10 were of London residents recorded in the Metropolitan Asylum Hospital at Durdorf, 4 in Edmonton, and 2 in Isleworth sub-districts).

SEWAGE AS AN EVANGELISING AGENT.—The *Sanitary Engineer* of New York is responsible for the following amusing mixture:—A reporter had to attend two meetings, one for the conversion of the Jews to Christianity, and the other, which followed immediately after, was on the subject of conversion of sewage into lime and cement. In the former's hands the folios got mixed up, and the report read: 'The chairman, after the meeting had been opened with prayer, explained that the conversion of the Jews was one of the greatest works that could engage the attention of our sanitary authorities. Filtration was the most perfect method that could be adopted for purification, but a flaw had its limits. There was a popular notion that the sewage contained a vast amount of wealth, but the sludge must be taken out of it for purposes of irrigation, as it otherwise choked the pores of the land, and they were a wandering race spread over the whole face of the habitable globe. They were denied the inimitable blessings of Christianity, which might be counted by thousands of tons per annum allowed to run to waste, when by a judicious admixture of lime and clay, the benighted Hebrews who sit in darkness might easily be converted into lime and cement for building purposes, and if thus deodorised, after being first dried and burned in a kiln, this ancient race would once more take its proud position among the nations of the world. Subscriptions were earnestly solicited for the purpose, though he (the speaker) disclaimed any idea of making a profit out of the process, and, in conclusion, he urged increased efforts in the good work, showing that, thus deodorised by a very novel process of evangelisation in large tanks constructed for the purpose, the grateful Hebrews might flow over the land without injury to vegetation, while the expense of conversion, which was promising as rapidly as the best friends of Christianity could wish, would be more than repaid by the sale of the phosphate of lime and valuable cement for building purposes.

In the last number of the *Revue d'Anthropologie* a paper by M. Charpy on the xiphoid angle, which incidentally exemplifies the mischief done to the natural symmetry of the female figure by tight lacing and other vicious customs in the matter of dress. They more or less disfigure all measures of the thorax taken after thirty years of age, and reduce the angle in question from its normal 75° 35' or even 45°.

SPECIAL REPORTS.

IMPROVEMENTS IN THE MANUFACTURE OF COAL GAS.

(BY OUR SPECIAL COMMISSIONER.)

SINCE its first introduction, gas has year by year increased in consumption, notwithstanding that it has been more vilified than any other illuminant invented. True, it blackens our ceilings and is injurious to our gildings and hangings; and the abominable smell constantly being sent forth from gasworks by the withdrawal of the lime used in the process of purification and highly charged with sulphuretted hydrogen, which permeates the atmosphere for a considerable distance, is decidedly injurious to health. What, then, is the cause of this constantly increasing consumption of gas, in spite of the disadvantages attendant upon its use. The reason is that it is found to be the simplest means of providing a brilliant light, as well as a heating agent, a great economiser of time and trouble, as compared with other illuminants. It is at all times ready when wanted—a trusty servant that never fails us. It is affirmed by experts that gas is even yet in its infancy. If a gas can be made without the disadvantage of polluting the air with sulphuretted hydrogen, and where the gas itself can be manufactured of a purer quality, the greatest objections to its use are at once removed, and corresponding advantages from a sanitary standpoint are obtained. This desideratum is now within the reach of all gas companies: it cannot be said within the reach of all gas consumers, as, unless manufacturers of gas will avail themselves of it, consumers cannot share in its benefits. It is in the purification of gas that the greatest objection on public grounds lies, when the purifiers are opened, and the lime charged with the objectionable chemical already mentioned is discharged into the atmosphere. If a change in this direction is to be effected an alteration in the mode of purification must take place. That lime has an important influence for this purpose is well known, but the question has arisen whether it has been made use of at the proper stage of manufacture. It was in 1812 that Clegg introduced the wet lime process of purification, and, broadly speaking, this is the system that has been in general use ever since; but of late years attempts have been made to introduce the lime at an earlier stage in the manufacture. But it has been reserved for Mr. W. J. Cooper to reduce the deductions into a practical form. The inventor of the improved process introduces the lime in the first part of the operation instead of in the last. No alteration of plant is required, no expense even of the most trivial character is necessary, and it is difficult to understand how any gas company, having even its own interests only in view, can hesitate to adopt the new plan when its advantages are properly set forth.

At the Tunbridge Wells Gas Works, which by the courtesy of the directors I have had an opportunity of visiting, the Cooper system has been in use for the last ten months, to the entire satisfaction of the engineer, Mr. Dougall, and the inhabitants of the town. The testimony and experience of Professor Wanklyn, and Mr. R. F. Spice, C.E., who have closely watched the making of gas at these works by the Cooper process, are strongly in its favour. Mr. Cooper uses 'limed' coal instead of 'pure' coal for his process. The limed coal is made by taking quicklime, slaking it, and then mixing it with the coal, the proportions recommended being 2½ parts of quicklime to 100 parts of coal.

At Tunbridge Wells one of West's crushing machines is in use, which breaks the coal into small pieces and assists to incorporate the lime more perfectly with it. The limed coal is then put into the retorts, and the after process, until we come to the purifiers, is the same as that

of the old system. The advantages of using limed coal are, according to Professor Wanklyn (in which, however, it is only fair to say that Mr. Spice is perfectly in accord), as follows:—The coal yields a larger fraction of its nitrogen in the form of ammonia; it also yields a slightly larger fraction of its carbon in the form of the volatile compounds. It gives a *very much smaller* portion of its sulphur in volatile forms, and the non-volatile residuum, the coke, is found to be considerably improved in quality. In the distillation of the coal the lime forms, with the sulphur in it, sulphuret of calcium, which becomes so incorporated with the coke as to be quite inseparable from it, and when burnt this sulphuret of calcium, being in the presence of an excess of lime, remains in the ash, thus preventing the sulphur which it contains being given off in sulphurous acid, as is the case with coke made from coal only. Small as is the addition of lime to the coal and its after appearance in the coke, as above described, it has the effect of promoting combustion, as it acts as a conductor of oxygen, and causes the coke to burn more brightly and cheerfully—in fact, considerably better than ordinary gas-coke ever did or can burn. There has been no difficulty in selling this coke in the town, and the inhabitants speak highly of it. Having thus given the effect of the ‘liming’ on the coal, we find nothing different in the mode of manufacture until we reach the purifiers, the last process. Tunbridge Wells, for the size of the works, is remarkably well provided with purifiers, which has no doubt helped the engineer materially. In these purifiers, instead of the layer of oxide of iron and of lime, we find oxide of iron only in use, and these purifiers have not been opened for the purpose of revivifying or changing the material for nine months, and Mr. Dougall, the engineer, is of opinion that they may run another six months without requiring to be disturbed. A revivifying process is constantly in operation consisting of the admission of a little fresh air to the purifiers. By this means the process of revivification of the oxide of iron goes on simultaneously with that of purification, oxygen being taken up from the air, and admitted, and sulphur deposited in the free state in the material. Consequently, as Mr. Spice observes, the manufacture of gas is carried on entirely in closed vessels, with the comfort of knowing that if the lime process is adopted generally the olfactory nerves will never more be disgusted with the smell of sulphuretted hydrogen, or health injured by its inhalation, for it is one of the most important features in this arrangement that noxious gas is not given off by the purifiers. As to the quality of the gas, I have already said that one of the advantages of the limed Cooper system is that it yields a *very much smaller* fraction of sulphur in volatile form. It is well known that sulphur exists in crude gas principally in the form of sulphuretted hydrogen; but partly, also, of other volatile sulphur compounds. ‘The present regulations in London permit of 17 grains per 100 cubic feet in summer and 22 grains in winter. In the provinces the sulphur compounds rise in some instances to 40 and even to 60 grains.’ At Tunbridge Wells the amount of sulphur compounds in the gas has been as low as 3; but the average may be taken at about 12 all the year round. It must, however, be remembered, that this process is in its early infancy; and, in the opinion of the experts who have experimented with it, it is possible to reduce this product to nil with a little extra care. In fact, in one experiment made in the laboratory by the inventor, and related by Professor Wanklyn in a paper read by him before the Society of Chemical Industry, Manchester Section, Jan. 8, 1884, the absence of sulphur compounds was so marked that he recognised the gas as being fragrant rather than fetid; thus it appears that, by the limed coal mode of manufacture, it is possible to produce a perfectly pure gas, which, of course, obviates all objection to gas. Three important conditions in which the public are interested are fulfilled by the introduction of the limed coal process.

The air in the neighbourhood of gas-works is rendered pure by the non-evaporation of sulphuretted hydrogen, and the public health thus benefited. The gas rendered comparatively pure, and, probably, before long, absolutely pure, is free from the objections hitherto urged against it, while the advantages gained by the production of the improved coke are scarcely less than the others stated. A prospect of preventing the production of smoke without interfering with the susceptibilities of those who like their open fires, is opened up by placing within their reach a fuel that is not subject to any of the objections to ordinary coke, and is without smokeless. Had the late Dr. Siemens seen this coke he would have been delighted to find one of his most cherished notions so soon brought to a state of realisation. In looking at the commercial aspect of this invention, although it has no right to be weighed against public benefit, it is satisfactory to find that its adoption is beneficial to gas companies by the increased quantity of the products given off. There is a decided increase in the quantity of ammoniacal liquor, but this has varied at different gasworks where tests have been made, and, in Professor Wanklyn’s opinion, the arrangements for the collection and storage of the gas liquor in most gasworks, particularly the old ones, is very inadequate. Experiments made in the laboratory with limed and unlimed coal have shown that the former is capable of more than doubling the yield of ammonia; and the authority last quoted is of opinion that even on a large scale in gasworks similar results will soon be obtained, but at present the highest quantity realised has been about 9 lbs. per ton of coal, which is half as much more than the yield from unlimed coal. The increase in the quantity of tar at Tunbridge Wells has amounted to only two-tenths of a gallon per ton of coal, but on a large quantity of coal carbonised this gain would amount to a considerable item annually. The opponents of the process have urged that less gas can be obtained from the limed coal, but Mr. R. P. Spice has, I think, effectively proved that this is not the case, for in a special test made with 200 tons of limed coal and the same quantity of unlimed, 10 feet more gas was actually made, so the quantities made by either process may be put on a par, and the illuminating power of the limed coal gas is so very near to the other as, for all lighting purposes, to be practically the same. It is in reality some 0.14 in candle power less, its average light being 15.63 against 15.77 of the unlimed coal. This difference is too minute to be appreciable by consumers. This invention is very important from a sanitary point of view, and I know that many of your readers have the power in their hands to facilitate its adoption. Thoroughly convinced of the value of the system, Mr. Dougall at Tunbridge Wells will readily show every detail of the process. Although the limed process is applicable to every condition of gas making, I consider it of great value to those who manufacture it on a small scale, such as owners of mansions, factories, &c., the relief gained through not having to open the purifiers and discharge the highly-charged lime, and the absence of smell being great recommendations. A company has been formed to let the right for using Mr. Cooper’s patents by royalty, named ‘The Coal Distillation Company (Cooper’s patents), Limited,’ 18 Finsbury Circus, E.C., from whom all particulars can be obtained. This undertaking is being watched with interest by many, and it would be well if all authorities who are connected with the department of public health would inquire into the working of the Cooper process, with a view to obtaining its adoption in the districts in which they carry on their labours.

THE Conseil d’Hygiène et de Salubrité de la Seine has elected MM. Brouardel, Hardy, and Bezançon as their representatives at the International Congress of Hygiene and Demography, which will be held at the Hague on August 17 and 31.

COTTON SIZING IN ITS INFLUENCE ON HEALTH.

THE report of the commissioners, Messrs. J. H. Bridges and E. H. Osborn, who were appointed by the Home Department to inquire into the effects of heavy sizing in cotton weaving upon the health of the operatives employed is now being issued. The starting-point of the investigation, which was the outcome of a memorial presented by the Trade Union Congress, complaining of the injury inflicted on the workpeople by over-sizing and by the introduction of steam into the weaving sheds, was the report of Dr. Buchanan, who made an investigation into the subject as far back as 1872. Since that date many and marked changes have taken place. The practice of artificial sizing has steadily increased, and the demand for articles so prepared is much more extensive than formerly, while the quality of the size has changed not less than its quantity. The use of china clay, which, in the period described by Dr. Buchanan, entered into the composition of the size to the extent of 33 to 37 per cent., has very largely increased of late years. It is obvious, then, that the amount of dust in the sheds has been increased in proportion, the atmosphere would have been incompatible with respiration. This result has, however, not followed, since the manufacturers, though not, perhaps, on the ground of health, have taken extreme pains so to prepare the size that as little as possible of it shall be lost in the weaving. This object has been obtained by the addition of substances possessing an affinity for moisture by special processes of preparation. By rendering the atmosphere of the weaving shed artificially moist, the fibres of the warp are enabled to retain their weight of clay, with no greater loss by dust than was observed in the primitive days of clay sizing. With but two exceptions, dust was a notable feature in most of the weaving sheds. In one there was no occasion for heavy sizing, and in the other, where the proportion of size was very great, there was, however, but little dust. This was effected by the adoption of special modes of preparing and putting on the size, and it must therefore be admitted that the problem of weaving heavily-sized material without diffusion of dust is a soluble problem, and one indeed, where special skill has been used, that has actually been solved. An examination of the air, with reference to moisture, showed that the average amount of moisture in the weaving sheds was 5.38 grains per cubic foot, and the average percentage of saturation 76, a distinct increase as compared with the average moisture recorded in 1872, which was 4.5 grains. The excess over the moisture in the atmosphere outside was, in Dr. Buchanan's observations, 1.2 grains, while in the present instance it represented 2.38. This points unquestionably to an extension in the means adopted for damping the atmosphere of weaving sheds, which has tended to create a climate of a somewhat tropical and relaxing kind. In a series of observations made in 1873 of the air in the spinning-rooms of cotton factories, it was found that the average percentage of saturation in a large number of instances did not exceed 43, a state of things contrasting very forcibly with the percentage of 76 found in the sheds during the recent inquiry. It was frequently stated by the workpeople that their clothing never felt really dry even in the morning until after it had been washed; and to meet this difficulty it is suggested that the outer clothing worn by the operatives should be hung outside the weaving shed, so as to be free from dust and moisture during the hours of work. Particular reference is made in the report to the very imperfect ventilation of the workshops, and of the great need that exists for improvement in this direction. The satisfactory ventilation of these large spaces is no easy matter, but the commissioners lay stress on the fact that with exceedingly few exceptions no adequate attempt to solve the problem has been made. As regards the injury inflicted upon the operatives, injury was made of twenty-seven persons selected at random

by the commissioners, and of twenty-nine brought before them by the Weavers Association. The evidence, as might be expected, differed considerably. Out of the first group seventeen made no complaint, but five had known of others who had suffered from the damp or from dust, though they themselves had not been affected. The remaining ten stated that they had suffered more or less from the damp, principally in the form of bronchitis, rheumatism, and neuralgia. The more prominent symptoms of the twenty-nine persons brought forward by the Association were dyspepsia, nausea, vertigo, rheumatism, and bronchitis; and, as far as the nature of the inquiry permitted a judgment, it would seem probable that the state of ill-health had been—if not caused, yet at least considerably aggravated by the conditions of their work. The report goes on to say: 'It seems to be evident that these conditions are not such as to prevent that large proportion of workpeople whose constitutions are naturally vigorous from following their calling without serious inconvenience. But there remains the proportion, also very considerable, who have a constitutional tendency to one form or other of rheumatic, phthisical, or dyspeptic ailment. Such tendencies cannot fail to be intensified by working continuously in an ill-ventilated atmosphere, whether pervaded by mineral dust or rendered artificially damp. In summarising the results of their investigation, the commissioners recommend—(a) that the processes by which very large quantities of size can be incorporated with the warp without necessitating the diffusion either of dust or of moisture should become generally known and applied; and (b) that the sheds should be thoroughly and effectually ventilated. They are convinced that if this last object be realised, complaints of injury from dust and steam would shrink to insignificant proportions.

PROFIT IN STREET REFUSE.

AN AMERICAN DESTROYER.

To turn street sweepings and house refuse of all sorts into money is the object of a strange machine now ready for work at the Jackson Street (East River) wharf, New York, of the Street Cleaning Department. Of course the conversion is not direct. Rags, old iron, broken glass, bones, cinders, and coal, are the media of change. The machine, according to the *Metal Worker*, is simply a vast rag and bone picker of many Italian-power, working by steam. The idea is a new one. Less than twelve months ago the machine was erected by a stock company on the Jackson Street wharf. Most of the intervening time has been given up to experiment, but now, it is said, the machine is perfected, and will sift and reduce to its elements all the refuse of whatever description that may be brought to it, to the extent of 150 loads of 1,800 lbs. each in a day of ten hours. The average amount of stuff brought to this wharf is estimated at 40 loads per diem, so that the sifter cannot be worked to anything like its full capacity. Out of 100 loads of ordinary refuse thrown into the sifter, it is claimed, only about 30 loads remain to be sent down the bays in the scows, the rest being utilised in one way or another.

The sifting-machine occupies a space about 40 feet long by 10 feet wide, covered with a shed on the end of the wharf. This shed is approached from the street end by an inclined plane which reaches nearly to its roof. The ash and garbage carts drive up this plane to a chute, through which they discharge their contents into the sifter within the shed. The matter falls on a tray, which has a resemblance to an old-fashioned Venetian blind extended horizontally. The weatherers are so arranged that only narrow slits remain between them, through which nothing but fine dust can find its way. This tray is called the 'oscillator.' It moves to and fro in the direction of its length 250 times a minute, and, as it rocks, the stuff that has been thrown on it is distributed automatically along its entire length, which is about 10 feet. Two or three Italians stand alongside, and pick all the rags and scraps

of paper out of the mass. These are spread out near by to dry. All the fine dust falls through the slits in the oscillator into a narrow trough called the 'conveyor,' which will be further described presently. The solid residuum on the tray of the oscillator—the dust and the rags having been removed—is passed automatically into a vat of water called a 'washer.' The passage of a load of refuse through the oscillator takes about four minutes. In the washer the solid mass that comes from the oscillator is rapidly stirred up. All the straw, fragments of leather, vegetable refuse, and other light material rises to the surface, whence it is removed by Italians to a cremating furnace, and reduced to fine ashes. The coal, cinder, iron, glass, and other heavy objects fall to the bottom of the washer. They are passed through a second vat to cleanse them thoroughly, and from this they emerge strewn on a broad rubber, which moves slowly over rollers. Italians stand on each side. They pick out the bones, pieces of iron, and glass, and stones. The belt discharges the coal and cinder, which remain in a heap. The fine dust which falls from the oscillator is kept in constant motion through the trough of the conveyor by means of a ribbon of metal twisted spirally about a shaft rotating lengthwise in the trough. The dust is taken up by automatic elevating buckets from the end of the conveyor, and by them discharged into the scow. The contrivance is said to be of advantage both to the city and to the stockholders, since, instead of 150 loads of stuff only 30 have to be transported. The stuff left is so clean and healthy that it can be used for any purpose. All the garbage is burnt, and only fine, dry dust put on board the scows. The rags fetch about 20 dollars a ton; the old iron 40 cents. per 100 lbs.; broken glass is worth 30 cents. per 100 lbs.; bones are more valuable. Out of every load of 1,800 lbs. about 400 lbs. of coal and cinder are got, which is all the fuel needed to keep the machinery going.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

'Something attempted, something done.'

BERKSHIRE COMBINED.—Dr. Woodforde evidently devoted a large amount of attention during 1882 to the question of water-supply in this district, and he could scarcely have turned his energies to a better channel. It was hardly to be expected that the high standard of health which was reached in 1881 would be maintained. Nevertheless the statistics cannot be considered by any means unsatisfactory. The rates for deaths and births per 1,000 population were relatively 16 and 31. In Bradfield the rate of mortality was only 13.8; in Wallingford Urban it was 24.9. The births in the Rural Division of Newbury amounted to but 26.7 per 1,000 living; in the Urban Division of this district they amounted to 34.5 per 1,000. Something over 13 per cent. of the total deaths, or 2.1 per 1,000, were registered from the principal zymotic diseases. The zymotic death-rate was lowest in Bradfield, where it was .4, and in Easthampstead Rural and Abingdon Urban it was only 1.7, but in Newbury Urban it was as high as 4.2. The most fatal of the disorders of this class in the district last referred to, as also in Hungerford, was scarlatina. Diphtheria was accountable for the heaviest death-roll in Newbury Rural, whooping-cough in Wallingford Rural and Maidenhead Urban, and measles in Windsor. The infantile mortality was at the rate of 98 deaths to every 1,000 births, while 32.9 per cent. of the deaths at all ages occurred in children under 5.

BETHNAL GREEN (ST. MATTHEW).—It is much to be regretted that the Vestry of this parish did not adopt the excellent recommendation of Dr. Bate that there should be a house-to-house inspection of the whole district during 1882. As the medical officer very properly puts it, 'such an inspection is urgently required to ascertain the condi-

tion of the drainage and water-supply arrangements,' and until it is carried out a large number of serious sanitary defects will doubtless continue to exist. Another matter for regret in Dr. Bate's report is that he has still to include a disinfectant among the sanitary requirements of the parish, and we heartily join with him in expressing a hope 'that the Vestry will shortly see its way to provide this very necessary apparatus.' The general health of the parish did not show much variation with that of the previous twelve months; indeed, the birth- and death-rates were practically the same as in that period, being respectively 41 and 24.1 per 1,000 population. There was a diminution in the zymotic death-rate, which, per 1,000 living, was 4.4, against 5.2, but an increase in the infantile mortality, which, per 1,000 births registered, was 164.7, against 153.5. With regard to the zymotic mortality, the deaths from small-pox, measles, and, to a less degree, diarrhoea and enteric fever, were fewer than in the previous year, but those from scarlet fever and whooping-cough were in excess of the numbers recorded for 1881. Of the 555 deaths referred to the principal zymotic diseases, scarlet fever and whooping-cough together accounted for 361 deaths. In respect of the infantile mortality, 27.3 per cent. of the deaths from all causes were those of children not twelve months old, and more than 90 per cent. those of children who had not attained their fifth year. Dr. Bate fortunately regards his duty of reporting to be not limited to a mere dry elucidation of the health statistics of the year. He discusses with much pains a variety of matters affecting the general sanitary welfare of the metropolis, and gives especially a very remarkable account of the present state of the disused burial-grounds of the parish.

BIRKENHEAD.—'The ordinary sanitary operations,' Mr. Vacher states, 'received unremitting attention' during 1882. The medical officer refers to the fact that the department is not provided with a night inspector, and it is certainly desirable that such an addition should be made to the staff. The vital statistics, though they did not reach the high standard of the previous year, were more favourable than usual. The birth- and death-rates were respectively 36.45 and 20.11 per 1,000. From all the zymotic diseases the rate of mortality was 3.68 per 1,000, and from the principal members of the group 2.9. Whooping-cough, of this class, accounted for the largest number of deaths. 'Fever' also were attended with more than ordinary fatality. The deaths from diarrhoea were in excess of those for 1881, but within the average. Scarlatina and diphtheria were prevalent throughout the year, and measles particularly so in October and November, but the mortality from these diseases was lower, not only than the average of the previous quinquennium, but even than in 'the typically healthy year 1881.' A large amount of interest always attaches to infantile mortality. In this borough during 1882 the deaths of infants under one year were in the proportion of 144 to every 1,000 births, while 42 per cent. of the total mortality occurred in children not five years old. Mr. Vacher speaks in the highest terms of the usefulness of the compulsory notification of infectious diseases, which is in force in the borough.

BIRMINGHAM.—Sanitary work was carried on energetically in this borough during 1882, but Dr. Hill is not yet able to report an improvement in the condition of the street surfaces, and has again to urge the necessity of a more complete system of scavenging. The want of a Public Abattoir is still felt, and seeing that such an institution, apart from its desirability from a sanitary point of view, would, judging from the experience of other towns, return a very fair profit, it is somewhat surprising that the want has not been supplied long since. The general death-rate, 20.6 per 1,000, was slightly in excess of that for the two preceding years, but, with these exceptions, was the lowest on record. A greater number of cases of small-pox were reported than in any year since 1875. In the year under notice, it was fatal in 17 cases only, com-

174 in 1875, and a decennial average of 125. In the fatality of the disease was no doubt every great measure, to the large extent to which ants of the borough avail themselves of vaccination, fever caused 256 deaths, against an average compared with the fatality of previous years, disease was particularly prevalent, the deaths in 1880, was, with these exceptions, the lowest since 1870. Diarrhoea contributed a number of deaths than in 1881—534 out of a total from all diseases of its class—but fewer than the average. Of the total mortality, 20.3 per cent. were due to zymotic diseases. The deaths among the population at the rate of 165 to every 1,000 births, and of the total mortality—47.2 per cent.—occurred under five. The birth-rate was 36.39 per 1,000. The sanitary work of the borough continues to be well pushed forward.

Measles was more than ordinarily destructive, but had not been so mild in any previous year. The death-rate from fever, 0.21 per 1,000, though slightly higher than for the preceding year, and showing no reduction for 1880, was, with these exceptions, the lowest since 1870. Diarrhoea contributed a number of deaths than in 1881—534 out of a total from all diseases of its class—but fewer than the average. Of the total mortality, 20.3 per cent. were due to zymotic diseases. The deaths among the population at the rate of 165 to every 1,000 births, and of the total mortality—47.2 per cent.—occurred under five. The birth-rate was 36.39 per 1,000. The sanitary work of the borough continues to be well pushed forward.

UNION.—It is obviously most essential that the arrangements of any seaside resort should be such as to enable the officials of this district have done well in a portion of their attention during 1883 to the abatement of the disease. Improvements were effected in the system, though there still remain several defects to be remedied, and, in addition, a thorough examination of the water supply, the result of which was satisfactory, since, in the opinion of the medical officer, the salubrity of the locality 'is in no way impaired by the condition of the water supply.' The death-rate from fever was 15, and the birth-rate 26.7 per 1,000 of population. The rate of mortality from zymotic diseases was 1,000, which was higher than it had been in previous years. The increase was due to an excessive mortality from scarlatina. The severity of the disease may be judged from the fact that of the 30 deaths registered during the year 16 were ascribed to scarlatina. Dr. Gatti attributes more than one outbreak to Great Britain, and, to judge from his report, the laxity of the officials of this town in the removal and isolation of persons infected with diseases is deserving of censure. On occasions, Dr. Domenichetti had to resort to the closure of a school, but, nevertheless, he records his opinion that it is inadvisable to close a school whenever an infectious nature makes its appearance, and, of his contention, states that, in one village, scarlatina prevailed extensively, the principle of isolating infected families was carried out with such results that only one death occurred during the year.

The infantile mortality was at the rate of 3.54 per 1,000 population.

BY UNION.—The year 1883 was the tenth anniversary of the appointment of health officers in this district, and the sanitary work accomplished during that period is shown by vital statistics. To this we have already referred on page 553 in the *Summary*. With regard to the year 1883 itself there is little to remark. Perhaps the most noteworthy feature of the year's history was the increase in the number of deaths from lung diseases among infants and aged persons. As a consequence, the death-rate—15.90 per 1,000—was still low, was higher than in any of the preceding years.

END OLD TOWN.—A large amount of useful sanitary work was done in this district during 1882-83, and there is nothing to refer to specially. At a time

when the housing of the poor is occupying such a large share of public attention, it may not be uninteresting to record Dr. Corner's opinion that the Artisans' and Labourers' Dwellings Act (1868) 'has proved most successful in his district.' In the period under consideration the medical officer reported upon seven houses under this Act. The vital statistics cannot be regarded in an unfavourable light. The deaths, which occurred at the rate of 20.87 per 1,000 population, showed a decrease of 69 compared with the average of the five previous years, and this notwithstanding that there has been a large increase in the population. The infantile mortality, amounting to 28 per cent. of the total deaths, was, it must be admitted, excessive; but this heavy proportion is somewhat discounted when it is considered that the birth-rate was as high as 38.6 per 1,000. Scarlet fever was the most fatal of the chief zymotic diseases, the death-rate from which was 3.23 per 1,000, or, exclusive of diarrhoea, 2.68.

MONMOUTH, RURAL.—The fact that every part of this district was visited during the year by the medical officer, Dr. Willis, and the inspector is of itself a sufficient proof that sanitary matters were by no means neglected in 1883. Two incidents in the year's history are especially worthy of notice. One was a peculiar outbreak of bastard or German measles, which occurred at Lydbrook towards the end of December. As many as 200 children were suffering at one time with this complaint. There is little doubt that the infection was spread by the attendance at the Church School of children from the Ross Rural District, who were sickening with the malady, which was of such an infectious nature that in an extremely short space of time every child in that portion of Lydbrook which is within the Monmouth Rural District had contracted the complaint. Fortunately the disease was of an exceptionally mild type, and the greater number of the patients were confined to their beds for one day only. The second incident was the almost simultaneous sickening and death of three children of a certain family residing in West Dean. The nature of the illness was very obscure; apparently the cases were dysenteric; the children were all imbecile; and on investigation the conclusion arrived at was that they had possibly eaten some poisonous plants in the woods which they frequented. The general death-rate for the year was 17.05. The most noticeable feature with regard to zymotic diseases was the prevalence of scarlet fever and whooping-cough, particularly of the former, which was widespread throughout the district during the year.

NEWINGTON.—Sanitary improvements were steadily carried on in this parish during 1882, but no work was accomplished of sufficient magnitude to warrant special reference to it in these pages. Taken as a whole, the vital statistics did not compare favourably with those of previous years. Dr. Iliff has to record the greatest number of deaths hitherto registered in a single year—viz. 2,704—which were equivalent to a rate of 24.80 per 1,000 population. The increase in the mortality was especially noticeable among the young, 1,333 deaths occurring in children under five years of age. In 716 of these cases death intervened before the completion of the first year. Zymotic diseases were fatal in 626 instances, 117 of which were referable to measles and 240 to whooping-cough, both these disorders being exceptionally prevalent. There is nothing to mention with regard to the remaining zymotic diseases, unless it be that there was a considerable diminution in the mortality from diarrhoea. An outbreak of measles of an extremely malignant type occurred in the Newington Infirmary in May. The deaths in this institution during the year (467 in all) showed, however, a decrease upon the numbers recorded in recent reports. On the other hand, the mortality among the outdoor poor was in excess of that of the two preceding years. As far as this individual class was concerned, small-pox, erysipelas, and insanity were on the decrease, but measles and whooping-cough on the increase.

ROMFORD RURAL.—Taking this district as a whole, its sanitary condition is extremely bad, and it is satisfactory to find that the authority's officials are doing what they can to remedy existing evils. We read with pleasure in Mr. Wright's report for 1883, that an extensive and apparently complete system of sewerage for Ilford, Barkingside, and Chadwell Heath, was in contemplation, and if this scheme be carried out, a step will be taken in the right direction. The general rate of mortality for the year was 16·03 per 1,000, while the death-rate from zymotic diseases alone was 1·3. Diarrhoea was attended with less fatality than in any previous year, but typhoid fever and diphtheria, owing chiefly to imperfect sanitary arrangements, prevailed to a considerable extent. One outbreak of diphtheria was especially illustrative of the connection between the disease and sanitary defects. In this instance two fatal cases occurred in a house where there was internal connection between the sink and the drain, thereby permitting the escape of sewer gas into the house. A recommendation to remedy this arrangement was not acted upon until another case had shown itself, when the requisite alterations were made, with a result that the disease did not again appear. The birth-rate for the year was 34·4 per 1,000.

SAINT GEORGE-IN-THE-EAST.—The health returns of this parish for 1882 will compare favourably with those recorded in many previous years. The chief cause for satisfaction is to be found in the great diminution in the deaths from zymotic diseases, which fell from 215 in 1881 to 153 in 1882—the year under consideration. The decrease was most marked in the deaths from measles and diarrhoea. Only 11 per cent. of the total deaths were attributed to diseases of this order, which is the lowest proportion that Mr. Rygate has yet recorded. There was some increase in the deaths of children under one year of age, as compared with the total deaths at all ages, the percentage being 28·4, against an average of 26·7. Nearly half the entire mortality occurred in children who had not attained five years of age. During the year there were registered 1,929 births and 1,197 deaths. Compared with the average of the ten preceding years, the births showed an increase of 60, and the deaths a decrease of 44. A little more information as to the sanitary progress of the district would have been acceptable.

SALFORD.—In his annual report for 1882, Dr. Tatham has again presented a very comprehensive account of the sanitary condition of this borough. It is a matter for regret that the medical officer should have so repeatedly to urge upon his committee the necessity for action in the matter of providing public abattoirs, and, looking to the benefits which would doubtless accrue to the district from the erection of such institutions, we trust that when Dr. Tatham has next to revert to this subject he will be in a position to state that his frequent appeals on this head have at length met with a response. The vital returns, though not quite so favourable as those of the preceding year, which was an exceptionally healthy one, were highly encouraging. The birth-rate, was identical with that for 1881, 38·8 per 1,000. The death-rate 23·2, was a shade over that for the previous year, but, with this exception, was the lowest on record. It must be a source of no inconsiderable congratulation to Dr. Tatham that he should be enabled to point out that, as compared with the average of the seventeen preceding years, 'the rate of mortality in 1882 was lower by not less than 16 per cent.' The zymotic diseases contributed somewhat under a fifth of the total mortality, or 4·5 deaths per 1,000 population. Of the six principal diseases of this class, the deaths from which were equivalent to only 2·7 per 1,000, against an average of 3·9, measles was the most fatal. This disorder accounted for 157 deaths, or 0·90 per 1,000, compared with an average of 1·44. Scarlet fever, which usually heads the list, took second place in 1882, with a death-roll of 81, or 0·44 per 1,000, against an average of 200. Small-pox, which had shown itself at the end of the previous year, was discovered in 73 cases, of which 18, or

one-fourth, did not recover. There was a considerable diminution in the fatality from fever, the death-rate this disease being only 0·34 per 1,000, compared with an average of 0·64. Diarrhoeal diseases were registered 240 deaths, or 1·30 per 1,000, against an average of 322.

STALYBRIDGE.—In his report for 1883, Mr. Dudley speaks in very high terms of the sanitary condition of this borough, which he describes as being 'thoroughly satisfactory.' 'The drains and ash-pits,' he states, 'looked after, and kept in good order. The water is of the purest kind, and second to none in the kingdom. It is not surprising, therefore, that, in a borough possessing these manifold advantages, there should have been a comparative scarcity of zymotic disease in 1883. The zymotic death-rate, which, on seven occasions during the previous nine years, had exceeded 3 per 1,000, was only 1·3. The decrease was striking in the case of whooping-cough, from which complaint not one death resulted, while only 15 deaths were referable to diarrhoeal disease—a number considerably below the average. It is to be observed that the scarlet fever were of an exceptionally severe nature, less than 9, or 1 in 4, of the 34 cases reported, being fatal. Comparing the deaths in infants with those registered, the proportion was 128 per 1,000—more favourable ratio than usual. The general mortality during the year was 21·5 per 1,000, the rate being 30·3.

ST. GILES'S.—The year 1882 was marked in this parish among other incidents, by the completion of the Mortuary and Coroner's Court in Goldsmith Street Lane. The ordinary routine of sanitary work was pursued, the inspectors making 11,776 visits and inspections, and serving 1,318 orders on owners of property for the abatement of nuisances and the improvement of premises. Both the birth- and death-rates—29·7 and 24 per 1,000—were above the average. Infants died in the proportion of 15 to 100 births, and 41·3 of the total deaths were children under five years of age. The zymotic death-rate was 3·3 per 1,000. Of the diseases of this class, scarlet fever was by far the most fatal, accounting for 41 deaths, a total of 156. Diphtheria, too, which was widespread all London, was especially disastrous in this district compared with previous years, being credited with 12 deaths, against an average of 4·2. The mortality from the rest of the zymotic disorders was not so high as customary. It is a significant fact that not a single case of typhus was reported. The entire absence of this disease was largely due, in Dr. Lovett's opinion, to the disinfection which has taken place of late in the courts and in Drury Lane, Little Cornam Street, and Great Street.

STOURPORT.—In his first annual report—that for 1882—Dr. Masterman expresses his conviction that the dampness of the air, overcrowding, and personal uncleanness, are the principal factors of disease in Stourport; 'the use of some habit the lower and lower-middle class have almost universally sleeping in the flannels they have by day, being an especially active one.' To the humidity of the air Dr. Masterman largely ascribes the prevalence of Bright's disease, and to the same cause, coupled with the extensive use of hard cider, he attributes the frequency of rheumatism. The chief sanitary needs of the town, he states, appear to be drainage, the more judicious use of the Kidderminster water, efficient scavenging, paths, and—rather as works of private benevolence—of the Board—a cottage hospital and public wash-house and wash-bouse. It is gratifying to learn, in Dr. Masterman's report for 1882, that considerable improvement have been effected in the scavenging system, and in the surface drains, though ventilating-pipes are needed at several points, for it is futile to shut in sewer gas; it must be conveyed harmlessly away. The condition

mpton Canal, which passes through Stourport, condemned by Dr. Masterman, who contends section within the town limits should be examined, summary, thoroughly dredged, and that the many which open into it should be cut off, though that, in the latter case, the canal 'is more sinned an sinning.' In 1881 the birth-rate was 39.63, death-rate 15.79; in 1882 these rates were respectively 39.33 and 16.09. Enteric fever was introduced district in 1882, and scarlatina, of a mild yet dangerous, was prevalent. The cases of enteric fever did to have originated in a place called Wilden, source of the disease was traced to the polluted well. In several instances, the fever was spread by overcrowding of a most revolting nature. The cases belonged to the series of secondary origin, stated to Dr. Masterman's mind very grave doubts innocuousness of sewage farms. The health officer probable that part of some cesspool soil, which shot into a field, was carried by the wind in fine fell into the pails used for drinking-water, which ding at the doors of some cottages adjoining the he cases of enteric fever generally pointed to the agonism of the disease, as not one of the attention on the sick was attacked by it.

FORD-UPON-AVON COMBINATION (RURAL).—The most interesting feature in Mr. Fosbrooke's 1882 is his account of the outbreak of typhoid Evesham, to which we referred at length on Vol. xiv. The epidemic of typhoid increased of mortality, per 1,000, from zymotic diseases, in it in which it took place, to 1.1, as compared with e previous year. In Alcester, the corresponding , was also higher than in 1881, owing to the extra om measles. In Stratford, the rate was 0.8, a ve that for 1881. The general death-rate, per 1 each of the three districts, was, in Stratford, Alcester, 15.8, and in Evesham 13.3. Owing sub-registrars not having made any returns the, Mr. Fosbrooke was unable to give the several en, and, what is still more important, particulars the mortality. It is to be hoped that arrangements ade to prevent so serious an omission in future.

The usefulness of combining the reports upon and urban districts under his charge, has long ted out by Mr. Fosbrooke, but his authorities made pt during the year to bring about the desired result. lical officer inveighs at some length on the evils om the defective drainage of the district.

FORD.—The sanitary department of this district to have done its work well during 1883. Mr. r states that 'great improvement was made in and sewerage yards and passages,' and that the of the township was, at the date of his report, mplete. Considerable attention was given to the of water supply. In several cases well water was ed, and the public water supply of the town sub-

The birth-rate for the year was 28.65, and the te 15.3 per 1,000 population. The deaths from diseases alone were equal to 1.45 per 1,000 persons Nearly 30 per cent. of the deaths were in children years of age.

RD UNION.—Both the water supply and the system of this district still continue in the same etory condition. In Mr. Partridge's report for read that in one of the villages, Minchin Lamp- ag to the generosity of a resident, the old sewage g improved and extended to the bottom of the it it is high time that the authority took the im- nt of the water supply and the drainage of the strict seriously in hand. The birth-rate for the 26.6, and the death-rate 15.9 per 1,000. The te was the lowest hitherto recorded, and so, with prisons, was the latter. Again, the percentage of om zymotic diseases, 5.2, was more favourable

than in any previous year, 1879 excepted. The infantile mortality represented 10.9 per cent. of the total deaths. It is a matter for regret that 25 per cent. of these deaths should have been referred to 'unknown' causes.

SUNDERLAND (PORT).—Of the 9,000 ships which entered this port during 1883, 3,101 were inspected, and of these 80½ per cent. were found in a sanitary, and 19½ per cent. in an insanitary, state. Some evil was still found to result from the storage of ships' stores in the fore-castles; but, on the other hand, an improvement was noticeable in the sheathing of iron decks. The condition of vessels belonging to this country, of which those of Sunderland bore off the palm, was, in most instances, superior to that of the vessels of other nations, though Mr. Harris speaks in high terms of the manner in which the Danish and Dutch ships are kept. It says much for the officials of this authority that captains of vessels should give their assurance that their ships are more systematically visited in Sunderland than in any other port in England. Although only one case of infectious disease was found during the year on vessels entering the port, the question of hospital accommodation is one which demands immediate attention, the more so since, as Mr. Harris points out, the authority is entirely dependent upon the urban authority (which is itself sadly deficient in this respect) for the means of isolating persons arriving from sea with diseases of an infectious nature. Unfortunately, in consequence of the narrowness of the river, it does not appear practicable, without danger to the public at large, and interference with navigation, to establish a floating hospital. The authority, however, seem to be alive to the importance of the subject, and have passed a resolution with a view to facilitate the provision of suitable accommodation for isolation.

WANDSWORTH.—It is satisfactory to find that the sanitary work carried out in this district annually increases in extent, but there are still several defects of great magnitude which it is of essential importance should be remedied, and to which attention is drawn in the annual report of the health officers for 1882. Among these more serious sanitary defects may be mentioned imperfect scavenging, inefficient sewer ventilation, and, chief of all, impure water supply. With regard to this last subject it is suggested that a supply should be obtained from the chalk strata by means of artesian wells, since 'no amount of filtration can completely remove the large quantity of organic impurity contained in the Thames water.' The vital statistics for the year under report were, with the exception of those for the period immediately preceding, the most favourable on record. The birth- and death-rates were respectively 35.69 and 17.48 per 1,000. This latter rate was 0.32 per 1,000 in excess of that for 1881, owing to a greater fatality from epidemic diseases, but 1.62 per 1,000 below the decennial average. The infantile mortality was equivalent to 137 deaths per 1,000 births—a more favourable proportion than usual. The mortality in children under ten increased, however, during the year, representing 51.3 per cent. of all deaths, against an average of 49.7. The deaths from the seven principal zymotic diseases—615 in number, or 43 less than the average—occasioned 15.9 per cent. of the total mortality, and 2.79 deaths per 1,000 population. Whooping-cough was the most fatal of these disorders, followed by scarlatina, diarrhoea, and measles. The deaths from whooping-cough, scarlatina, and measles were respectively 26, 5, and 23 above the average, but those from diarrhoea were 68 below the average. Diphtheria was particularly fatal in Putney, where it caused 29 deaths out of the 51 registered for the whole district.

WEST SUSSEX.—Dr. Kelly has treated the vital statistics of this district very exhaustively in his report for 1882. The year's history, however, presents nothing of extraordinary interest. The birth-rate, 30.9 per 1,000, differed scarcely at all from the rates recorded in previous years. As usual, there was an excess of male over female

births, the respective numbers being 1,592 and 1,381. It is worthy of note that, during the period 1876-1882, the births were twice as numerous as the deaths. The general death-rate was 14.3 per 1,000, a trifle above that of the previous year, but, with this exception, the lowest recorded. The infantile mortality, in proportion to every 1,000 children born, was 90, showing a decrease on the average of 3 per 1,000. The zymotic diseases accounted for 164 deaths out of a total of 1,376, or 1.7 deaths per 1,000 population. To whooping-cough 53 deaths were registered; to diphtheria, 35; to diarrhoea, 19; to measles, 16; and to scarlatina, 15.

WITHINGTON.—The officials of this district appear to have done their work very thoroughly in 1883. Among other items, it is pleasing to find that 'the number of houses supplied with water from springs and pumps is steadily diminishing.' It is worthy of note that the magistrates decided that, although the keeping of pigs may be proved to be a nuisance, the Board have no power to compel the owners of these pigs to discontinue keeping them. Dr. Railton points out that it will probably become necessary to establish a by-law limiting the distance from dwelling-houses at which pigs may be kept. The vital statistics for the year are satisfactory, the death-rate, in spite of an increased birth-rate—31 per 1,000—being only 13.4 per 1,000. Zymotic diseases showed a death-rate of 1.4 per 1,000. Of disorders of this class, scarlet fever was exceptionally prevalent, more so than in any preceding year. With reference to the infantile mortality, it may be mentioned that fully one-fourth of the total deaths occurred in children under five years of age, nearly 50 per cent. of whom died before they had completed one year of existence.

WORSBROUGH.—It is gratifying to read in Dr. Sadler's report for 1883 that the water-supply of this township is 'unexceptionable,' and that the system of sewerage and sewage disposal, which was considerably improved during the year, is 'complete for all its more important portions.' The scavenging of the district, however, is very imperfectly carried out and requires serious attention. Dr. Sadler has done wisely in adverting betimes to the condition of the burial-grounds of the township, which, in his opinion, is such that it will be necessary to provide further accommodation in this direction within the next two years. The birth and death-rates for 1883 were respectively 39.40 and 17.77 per 1,000 population. The infantile mortality was in the ratio of 162 deaths to every 1,000 births, and over 56 per cent. of the total deaths occurred in children not five years old. There only remains to add that zymotic diseases were accredited with 22 deaths out of an aggregate of 150.

NEW INVENTIONS.

THE BOLANACHI COMPANY'S NEW CHOCOLATE.

IN this country chocolate is not drunk to the same extent as on the Continent, although the cacao bean is much consumed in the form of chocolate confectionery. The cacao bean, when ground and mixed with certain ingredients, forms a large percentage of the beverages in use in England, particularly amongst the poorer classes, who like it for its palatability, and also because it is more nourishing than tea or coffee. That cocoa is, as a matter of fact, looked upon with favour by all classes, is shown by the many preparations of it that have been introduced, at prices to suit all sections of society. Some preparations are recommended because the butter has been extracted, and others because it is retained. Cocoa, however, is a beverage that may be sold pure at a price within the means of the working classes, and yet, because it is one of the easiest things possible to adulterate, an undue proportion of starch and flour, if not more unwholesome ingredients,

is often mixed with it, so as to reduce its nutritive properties to a low standard. These reflections have been suggested by a recent visit to Bolanachi's Chocolate Company's Manufactory, at Spa Road, Bermondsey, where chocolate is being made on an extensive scale by an entirely new and simple process, the invention of Mr. Bolanachi, who has devoted many years of thought and experiment to the subject. These experiments have resulted in his being enabled to offer the public a pure compound of delightful flavour at a price that brings it within the reach of all classes. Chocolate is the name given to a compound composed of a certain portion of the cacao bean, sugar, and some kind of starchy matter, but Mr. Bolanachi discards the latter altogether, and instead of the sugar he uses a syrupy honey-like extract, obtained from the Ceretonia bean (*Ceretonia siliqua*), popularly known as St. John's bread, and of this and the cacao bean in its pure state the new chocolate is exclusively made. The inventor, who is of Turkish nationality, and whose family are extensive landed proprietors in the Greek Archipelago, some years since conceived the idea that the Ceretonia bean might be put to more important uses than those for which it is generally employed, and commenced experiments with a view to extract its rich saccharine matter; of which the chocolate factory in the Spa Road is the practical outcome. A short description of the *modus operandi* will demonstrate the absolute purity of the ingredients and the exact constituents of 'Chocolate Bolanachi.' The cacao bean when roasted is relieved of the husk, which is not used at all, then roasted, ground, and mixed or worked by machinery, with the whole of its butter retained, and so formed into what is technically called cocoa cake. The ceretonia beans, of which only the finest qualities are used, coming from Candia and Cyprus, are also ground, and then carried by covered 'shoots' to a range of large circular vessels, where it is prepared ready for evaporation, the liquor passing down into a large receptacle, and by means of a steam pump it is eventually carried to a steam-jacketed pan, where it is evaporated, leaving only the rich, honey-like extract before named. Both ingredients are now ready for combination. Forty parts of the cocoa cake and sixty of the honey syrup are then placed in a machine of ingenious construction, where they are thoroughly mixed and incorporated, and eventually withdrawn in the form of a thick paste. It is then put into tins holding one pound each, covered and labelled, and packed in boxes ready for delivery. All the processes, which are very simple, and, except the filtration, comparatively rapid; are effected by machinery, and the hand does not come in contact with the ingredients at any stage. But the most remarkable effect of the combination of the two substances is the change effected as regards the cocoa butter. Were a portion of this cocoa cake, with all its butter in it, to be eaten, the probability is that the strongest digestion would not assimilate it comfortably, and a large percentage of people could not take it at all, but by its admixture with the syrup of the ceretonia bean this state of things is changed. Though still present, the butter is robbed of its objectionable properties, and when mixed with water, not a particle of fat is visible to the eye or perceptible to the palate. It is thus in the form of chocolate paste that this product is commercially introduced, and for the reasons that Mr. Bolanachi has been desirous to introduce it as a popular beverage, and at a price within the means of the poorer classes. As the two ingredients are, so to speak, 'cooked' in the process of preparation, nothing further is required than to take a spoonful of the chocolate and mix it in a breakfast cup with boiling water, where a delicious infusion is obtained, and unless the individual who is to drink it have a very 'sweet tooth,' no addition of sugar is required. If made with milk instead of water a much richer beverage is obtained; but in either case this chocolate is equal in flavour to the finest preparation of the kind obtainable. This paste is sold retail in one pound tins at one shilling, and although a little

price than some of the trash sold even as ordinary men its purity and sustaining properties are taken deration, it is really much cheaper. Although as introduced as a paste the chocolate cake will soon and arrangements are now in progress for making is kinds of chocolate confectionery so much liked blic. It is affirmed that the weakest digestion ilate this chocolate, and from trials the writer has th it he is disposed to support the assertion. advantage resulting from the manufacture (to the is that a good food for cattle is found in the , which can be supplied at a low rate. Mr. i has called in the valuable aid of Professor who has visited the factory and made himself d with all the processes, taking his samples for from bulk. The analysis appended is so satis- at there can be no reluctance in recommending late, particularly to those who are responsible for being of the poorer classes, or who are concerned : diet. Mr. W. W. Parkinson, the master of the st. Workhouse of the St. Olave's Union, South- s made experiments with one cwt. of the Bola- colate, and finds that, while yielding a much itious beverage than those now in use, the cost is atther less.

JOHN ATTFIELD.

A DOMESTIC CONUNDRUM.

the above title the City of London Sanitary ion, of Cannon Street, E.C., have patented a new

(of which an illustration is appended), and which

is further stated to be 'without a bottom, without a lid, and without a spout.' As the reader will gather from the drawing, it is intended to boil water rapidly, which from its shape it is bound to accomplish. It will be observed that it is formed with a large hollow chamber underneath, in which the fire or heat is concentrated, and the only orifice through which the water is poured in or withdrawn is the one on the right-hand side. It may be questioned whether the inventor, Mr. Barron, the manager of the company, has correctly described the kettle as being without a spout, neither do we desire or request a discussion of 'what is a spout,' but it can be entirely recommended as a valuable addition to any home, and for many purposes when a small supply of hot water is required quickly. It is made in various sizes. It matters not whether the applied heat be that of a fire, a gas stove, or a simple gas burner, as the great amount of caloric collected in the hollow chamber causes the boiling point to be reached in an incredibly short space of time.

LAW REPORTS.

JUDICIAL COMMITTEE OF THE PRIVY COUNCIL.

(Present.—SIR BARNES PEACOCK, SIR ROBERT COLLIER, and SIR ARTHUR HOBHOUSE.)

Bischof's Patent.

THIS was a petition for the prolongation of letters-patent granted on Sept. 19, 1870, for a term of fourteen years, to Mr. Gustav Bischof, jun., for the invention of 'improvements in the means employed for the purification of water.'

The invention related to the use of spongy iron for purifying water for domestic purposes, and depriving sewage of its obnoxious and dangerous properties. Spongy iron has been proved to possess a strong and lasting action in separating or destroying and rendering innocuous by chemical agency various objectionable matters occurring in water and sewage; and of still greater importance is the physiological purification effected by the material—that is to say, the destruction by it of low forms of organic life occurring in water and sewage. It has been proved that no degree of dilution and no natural filtration or ordinary artificial filtration, such as through sand, however efficient it may be, affords any such guarantee; and it had been applied with very great and most marked practical success at the military stations of Fort George, in Scotland, Shoburness, and elsewhere. The petitioners, Mr. Bischof and others, had expended large sums of money and devoted great pains and trouble in endeavouring to introduce the invention to the public and bring it to use. They had endeavoured to obtain its employment by water companies in London, but owing to the uncertainty which had prevailed since 1878 as to the position of the water companies in regard to proposed legislation on their rights, the companies had been unwilling to embark new capital in adopting the invention. The only town in which the invention had been applied to waterworks was Antwerp, and it had been perfectly successful. In these circumstances, the chief application of the invention had been for the purpose of the manufacture of domestic filters. The utility of the invention had been generally acknowledged, and domestic spongy iron filters had been introduced into the various Government departments, and were beginning to be generally used. In these circumstances, the petitioners asked to have the patent extended, in order that they might receive a fair reimbursement and remuneration commensurate with the great public value and importance of the invention.

Their lordships entertained no doubt that the invention which was the subject-matter of the patent was a very useful and meritorious one, and they thought that as far as that went it should be renewed, unless the patentee had received adequate remuneration. As to that point, the

accounts had been proved, and the Attorney-General did not object to them. Their lordships were of opinion, upon those accounts, that so far from the patentee having made any profit, he had sustained a loss, and they thought that they ought to advise Her Majesty to renew the patent. In the case of Spencer's patent, it was extended for seven years, and, following that precedent, their lordships would advise her Majesty to extend Bischof's patent for seven years.

ADULTERATION OF SWISS MILK.

Messrs. J. C. Flack & Sons, of 484 Bethnal Green Road, appeared at Worship Street to a summons under the sixth section of the Adulteration Act for having sold an article of food, to wit condensed milk, containing only one quarter of the usual proportion of butter fat. Mr. Lapworth, a sanitary inspector of Bethnal Green parish, proved purchasing at the shop of the defendants a tin of condensed milk, which was submitted to the parochial analyst. His certificate was now put in, and declared that the condensed milk in question contained 'only one quarter of the usual proportion of butter fat, the original milk was reduced in bulk from 4.96 parts to one, and had 26.07 per cent. of cane sugar added. Originally it contained only 0.52 per cent. of butter fat.' It was mentioned that although proceedings in connection with condensed milk had been taken by authorities in country towns, this was the first action of the kind in London. The defence was that the defendants were relieved from liability under the Act by the 25th section, which said that such exception should take place if the article in question was of the same nature, substance, and quality as purchased by the seller; that he had no reason to believe it was otherwise, and that he sold it in the same state as supplied, and with a written warranty. There was upon a label pasted to the tin the following words: 'The company guarantees this to be simply pure milk obtained from cows fed in the valley of Switzerland.' It was contended that this warranty, which was affixed to the tin, was placed by the original merchants; but the defendants were unable to state the actual name of the company who supplied them, through their agent. The defendants also proved that the tins sold were not tampered with before being retailed. The defendants did not contest the analysis. Mr. Hannay said he was inclined to believe the label was not a warranty within the meaning of the Act, and the only protection for retailers would be to procure a written warranty from the firm from whom they obtained their supplies. In the present case, no one could say who 'the company' guaranteeing was. The Act certainly intended that some one should be liable in these cases, and although he did not think the defendants were morally guilty, they would have to bear the responsibility. He imposed a nominal penalty of 1s., with 23s. costs. The defendants said they had stopped the sale of the brand in question.

THE ABSTRACTION OF CREAM FROM MILK.

An important case to milk dealers was decided at the last Birmingham Quarter Sessions. Ernest Bomford, a farmer, appealed against a conviction by two of the Birmingham borough justices for abstracting from milk sold by him 20 per cent. of cream, and not disclosing the fact. The proceedings were taken under the third section of the Food and Drugs Adulteration Amendment Act, of 1875, which makes it illegal for any person to abstract any food or sell any article adulterated without making it known. The analysis of the sample taken by the inspector showed the amount of fat to be 2.39 per cent., and of solids, not fat, 9.01 per cent. The standard taken by the analyst as the basis of his calculations as to the purity or otherwise of milk was 3 per cent. for fat and 9 per cent. for other solids. The defence was that the milk was pure as it came from the cow when it was delivered to the railway people, and that the adulteration, if any, was effected during transit and between the time of the delivery of the milk to the railway authorities and its reaching Snow Hill Station at Birmingham, where the

sample was taken upon which the proceedings were based. It was therefore a matter beyond the appellant's knowledge, and as such impossible for him to disclose. It was also stated that the railway company would not allow the churns to be locked unless they had a duplicate key. The Assistant Recorder, in giving judgment, stated he had no doubt the cream had been abstracted from the milk, while he was satisfied that it could not have been done previous to the milk being sent to the railway. It would be unwarrantable to hold the appellant responsible for failing to disclose a fact of which he could not possibly have any knowledge, and he quashed the conviction, with costs.

UNWHOLESOME FOOD.—TECHNICAL DEFEAT OF JUSTICE.

At the Darlington Borough Police Court, on the 24th ult., Richard Iddison, a butcher of Park Street, was charged by Mr. T. A. Atkinson, Nuisance Inspector of that borough, with exposing for sale a quantity of diseased meat. The Inspector stated that on the 7th ult. Iddison had about 15½ stones of meat, liver, kidneys, &c., which from its appearance he suspected to be unsound. Dr. Lawrence condemned the meat and had it destroyed. Mr. G. Maw, who appeared for the defence, took the objection that the appointment of Mr. Atkinson as Inspector of Nuisances had not been proved. The Bench dismissed the case, and a charge against J. Button, Park Street, was also dismissed on the same contention. This miscarriage of justice should be carefully noted by sanitary inspectors.

SMOKE ABATEMENT.

Messrs. Maybury, Marston, & Sharpe, hoop iron manufacturers, Brindle Heath, Pendleton, have been summoned to the Salford Police-court for permitting a smoke nuisance at their works, and fined 5l. and costs.

THE TIPPING OF REFUSE.

Action against the Darwen Corporation.

In the Chancery Court of Lancashire, at Manchester, before Vice-Chancellor Bristowe, George Walsh v. The Mayor and Corporation of Over Darwen, in which plaintiff sought for an injunction to restrain the defendants from continuing the tipping of refuse on land adjoining his house, has been before the Court. One of the plaintiff's witnesses, Mr. Beevers, of Preston, having stated that the Corporation had made arrangements for bringing the refuse complained of into the ravine near plaintiff's house by an entrance furthest removed from it instead of passing it, which would abate the nuisance to a considerable extent, the Vice-Chancellor suggested whether an arrangement might not be made between the parties. It was ultimately arranged that the matter should stand over until October next, the Darwen Corporation in the meantime to desist from conveying refuse past the plaintiff's house, it being understood that this was to be done without prejudice as to costs.

BRIEF NOTES OF USEFUL CASES.

HIGHWAY.

1883. *Carter v. St. Giles's B.W.* Application for Injunction to restrain the narrowing of a cartway by abstracting space for formation of a footway—Application refused, it being shown that a footway was desirable, and that defendants had not exceeded their powers. (*Times*, June 23, 1883.)

STREET IMPROVEMENTS.

1883. *Gard v. Commissioners of Sewers.* Local Act—Powers to take premises for widening a street restricted—*Thomas v. Daw and Galloway v. London* distinguished. (18 L.J., N. of C., 107; 49 L.J., 325.)

SCAVENGING.

1883. *Goodacre v. Watson.* Injunction granted at suit of neighbours to restrain land from being used for deposit of house refuse, before being built upon. *Per Fry, J.*—

'It was nothing short of horrible to think that persons should seek to place foul vegetable and animal matter as foundations for buildings, and then come into court to defend such conduct.' (*Times*, Feb. 23, 1883.)

GIFT TO CORPORATION.

1883. *Hewitt's Estate, In re.* Gift to Corporation of money, the interest to be applied in 'acts of hospitality or charity,' held void for uncertainty. (53 L.J., Ch., 132; p. 73 [*Hewitt v. Hudspeth*] 49 L.T., 587.)

RATING OF EMPTY HOUSE.

1883. *Hicks v. Dunstable Overseers.* Owner of empty house held rateable when he had put in a caretaker who made some money at a weekly rent out of the herbage. (47 J.P., 821.)

HIGHWAY.

1883. *Illingworth v. Bulmer East Highway Board.* 25 & 26 Vict., c. 61, § 18—Neglect to repair highway—Grounds on which an appeal to sessions might be had against an Order of Justices. (52 L.J., Q.B.D., 680; 48 J.P., 37.)

WHARF.

1883. *Lucas v. Sculcoates Assessment Committee.* Rating of wharf used by contractors engaged in making a railway. (At Q. Sess.) (47 J.P., 761.)

SEWER.

1883. *Metropolitan Board of Works v. Willesden Local Board.* Rights of local authorities just outside the metropolis to use of metropolitan sewers. (*Times*, Dec. 4, 1883.)

POOR RATE.

1883. *Peterborough Corporation v. Wiltshorpe Overseers.* An appeal lies to the Court of Appeal from a decision of the Queen's Bench on a case stated in an appeal against a Poor Rate. (53 L.J., M.C., 33; L.R., 12 Q.B.D., 1.)

COMPENSATION.

1883. *Pearsall v. Brierley Hill Local Board.* Public Health Act, 1875, § 308. A person claiming compensation may insist on amount being decided by arbitration, even though a dispute exists as to the liability. A valid decision as to liability is not a condition precedent to arbitration as to amount. (52 L.J., Q.B.D., 529; 49 L.T., 486; 47 J.P., 628.)

ROAD REPAIR.

1883. *Reg. v. Cheshire Jf.* Road out of repair—Dispute as to way being public or private—Quarter Sessions held bound to order an Indictment notwithstanding *Reg. v. Farrar*. (47 J.P., 788.)

DEFAULT AS TO SEWERAGE.

1884. *Reg. v. Cheshunt L. B.* Default of Board for several years to provide sewerage—*Mandamus* issued at instance of Local Government Board under 'Public Health Act, 1875,' § 299. (*Times*, April 3, 1884.)

RATING OF DOCKS.

1883. *Poplar Union v. East India Dock Co.* Annual profits steadily falling off—How changes in annual value to be dealt with for valuation purposes. (Metrop., 48 J.P., 116.)

SEWER EXPENSES.

1883. *Salford Corporation v. Clowes.* On proof that a road was an 'Occupation road' to two farms, adjacent owners held liable for paving and sewerage. (*Times*, March 23, 1883.)

RATES.

1883. *Yates v. Chorlton-on-Medlock Union.* Caretaker put into empty house with duty of showing it to intending tenants, and to go out on request, held not a rateable occupier, only owner's servant. (48 L.T., 873; 47 J.P., 630.)

REVIEWS.

Nineteen Centuries of Drink in England. By RICHARD VALPY FRENCH, D.C.L., LL.D., F.S.A. London: Longmans, Green, & Co. 1884.

THE author of this interesting book has evidently written it with the design to elucidate the part which intoxicating drink has played in the individual and national life of the English people. With this object he has conducted an elaborate inquiry into the various kinds of intoxicants in common use at different periods, into our drinking customs and usages, and into our drinking vessels, as well as into the many legislative and ecclesiastical attempts in our history to limit alcoholic indulgence. The ancient Britons led a generally abstinent life, but upon extraordinary occasions they drank to excess, and almost invariably quarrelled when in their cups. Before the Roman conquest wine was unknown in Britain, *metheglin* or mead having been the only intoxicant of which we have any record. After the introduction of agriculture, ale and cider became common drinks. The Romans introduced wine; and repeated, though practically unsuccessful, attempts were made for centuries to cultivate the grape for the manufacture of wine in England. To the Romans we also owe signboards. For ages the first sign of an inn was a bush; hence the proverb, 'Good wine needs no bush.' To the Roman influence, too, we are indebted for our national custom of toast-drinking, several classical authors abounding in descriptions of Roman toasting formalities. From these invaders our progenitors adopted habits of excess, all ranks and conditions of men becoming rapidly intemperate and luxurious in their mode of life. Though not a new plant of Saxon setting, intoxication increased so greatly during the Saxon period that even the clergy fell into the too fashionable vice, so much so that bishops themselves drank to excess and amused themselves by compelling others to drink till they were intoxicated. During this period the chief beverages were wine, mead, ale, cider, and piment. In the eighth century taverns or ale-houses had been established. In the Danish period drinking became still more widespread, a special feature of this period having been voluntary associations, *sodalitates*, designed as much for conviviality as for spiritual benefit. The battle of Hastings was lost through the debauchery of Harold's troops. The author describes the Plantagenet reign as the Light Wine period, a variety of light wines having at that time been introduced into common use, though he tells us that no improvement in public morals followed. He traces English drinking habits to the present day, and contends that, till recently, our national shortcoming had shown little appearance of diminution. He admits that there are now symptoms of a change for the better, quoting Isaac Disraeli's prediction of a return to sobriety. Dr. French refers to the various drastic endeavours both by Church and State to lessen the evil, but is unable to point to any marked amelioration from either ecclesiastical or legislative action. Contrary to what might have been expected from so noted an advocate of total abstinence, he seems to foreshadow a time when man shall forbear from abusing 'the gifts which a gracious Father has given his children to enjoy.' By this, we presume, he means that men shall learn to use without abusing strong drink, to drink moderately without going on to intoxication. We fear that this dream has little chance of realisation. So long as intoxicating drinks continue to be made as strongly alcoholic as most of them at present are, and so long as human nature remains fallible, we fear that intemperance will not cease in the land. As the public health has so severely suffered from the excessive use of intoxicants in the past, so it will in the future, unless either abstinence becomes more diffused through the population, or, as might easily be done, beverages with a lower alcoholic strength come into fashion. The book, which is tastefully got up, contains much valuable information.

Our Duty in Regard to Health. By G. V. POORE, M.D., F.R.C.P. International Health Exhibition Handbooks. Clowes & Sons, London.

WE have read through this little book with feelings of great interest. It is cleverly written and contains much that is good, though sometimes open to the venial charge of being in some respects unpractical. A main feature of it is an attack on the water-carriage of excreta, a sweeping condemnation of sewers and sewerage under all circumstances. Dr. Poore hardly seems adequately to distinguish between aggregation of population and overcrowding. Aggregation is a necessary concomitant of the growth of modern industries, commerce, and civilisation, and is not in itself incompatible with a high state of health. By overcrowding we understand such a herding together of the masses amid sanitary surroundings of a low order as is incompatible with health and morality.

However desirable it might be that every rood of land should maintain its man, as Goldsmith sang, or that every house should have a quarter of an acre of garden-ground wherein to dispose of the excreta, we cannot hope or ask for the return of such a state of society, and it is of no use 'crying for the moon.' We entirely agree with Dr. Poore in deprecating the introduction of sewers into country towns where earth-closets for the careful and pails for the careless would suffice for the reception and facilitate the utilisation of the excreta; but could such a scheme be carried out in London, or could Birmingham, Manchester, Liverpool, and Glasgow be now broken up and their houses be distributed over entire counties? If not, what other than sewerage and water-carriage can be pointed to as the best, the quickest, cheapest, and most cleanly way of conveying excreta away from the precincts of the houses? That the discharge of the sewage as such into rivers can no longer be tolerated we feel strongly, but since sewerage is a necessity we must on the one hand insist on the complete disconnection of every house from the sewer, and on the other on the treatment of the sewage by irrigation or chemical process, so as to render it sufficiently pure to be passed into large streams, where it may be subjected to the oxidising action of running water.

Again, is it practical to tell the Londoner, even if he enjoy his quarter of an acre of tennis lawn and flower garden, to deposit or bury his excrement therein. Surely, then, to tax water-closets would be cruel to the poor man and unjust to the rich. Dr. Poore wisely and emphatically points out the dangers of surface wells, or even of deep ones under certain circumstances; but it is another thing to insist on the exclusive use of rain and river water, since the latter is not always within reach, and the former, besides being uncertain in amount, requires precautions for its storage, which cannot be counted on in the cottages of the labouring poor to prevent its becoming fouler than the worst well or ditch.

The author's strictures on the practice of crowding one's guests in dining-rooms or saloons with less cubic space than is allowed to convicts, and on the abuse of dustbins, are worthy of the highest commendation. Indeed, the writer of this has himself dispensed with the dustbin altogether, finding the fowls, the kitchen fire, and the garden soil together capable of disposing of every kind of refuse, and realising the author's epigram that the dustman's call for the contents of a single pail, containing only broken glass and dry bones, need not take more time than the postman's visit.

As regards the disposal of the dead, Dr. Poore is in favour of interment versus cremation.

In conclusion, we can only repeat that the advice contained in this little book is applicable enough to the occupier of a country house or cottage, but that as regards the denizen of our existing large towns it can hardly be said to face the hard facts of the case, or realise the difficulties with which the practical sanitarian has to deal. None the less it is an intelligent, original, very readable,

and outspoken treatise, full of sound doctrine vividly enforced.

Where to take a Holiday: Reports on some Home and Foreign Health-Resorts, being the Holiday Number of the LONDON MEDICAL RECORD. London: Smith, Elder, & Co. 1884.

IN the SANITARY RECORD of August 15, 1883, we reviewed at length the first number of 'Where to take a Holiday,' which had then been just issued. The publication thus early in the present summer of this second number will be welcomed by many readers, as in many particulars it is a considerable improvement upon its predecessor. There seems in the present instance to be scarcely the same necessity to review the whole work in like detail as in August last; but, briefly, it may be described as a collection of papers on holiday topics by medical men, each of whom has evidently made himself practically acquainted with the subject on which he writes. They approach the question of 'Where to take a Holiday' from the physician's point of view, and show in what maladies and conditions of ill-health the various health-resorts in and within easy distance of the British Isles may be expected to be of service to invalids. There are many points noticed in the various papers that will be of service to holiday seekers in general, but by those who travel for health's sake, and by their medical attendants who, in all likelihood, are called to assist at the family council when the momentous question of 'where to go' is decided, these pages will be found particularly useful.

The following is a short summary of the papers herein published. The first is entitled 'The Spas of Great Britain,' and is from the pen of Inspector-General Macpherson. In it he classifies the spas under eight heads, and notices in detail the chief localities and towns at which the various kinds of waters are found, including Cheltenham, Leamington, Scarborough, Droitwich, Tunbridge Wells, Harrogate, Buxton, Matlock, and Bath in England, Llandrindod in Wales, Strathpeffer, Moffat, Bridge of Allan and other places in Scotland, and Lindisvarna and other localities in Ireland. Dr. Hermann Weber is the author of the second paper, which describes 'Continental Climatic Resorts in Summer' in a brief space, which all will do well to read who are seeking for information on this wide question. The accomplished author describes these resorts in the two natural divisions of seaside places and inland climates of the Continent. The choice of English health-resorts is described in the third paper, by Dr. Symes Thompson, under four heads: conditions which determine choice of change, health-resorts in general, seaside health-resorts, and inland health-resorts. Dr. C. Parsons contributes judicious remarks on sea-bathing in the next article. Dr. Burney Yeo describes a not too well-known holiday locality in an article on Pyrenean and adjacent Summer Health-Resorts, from which those who are seeking for fresh lands for their holiday-feet to conquer may gain much instruction. Dr. Thin shows how summer holidays at sea may be enjoyed in cruises in the many lines of steamers which take their departure from British shores. Lastly, Dr. Vintras, in continuation of his paper of last year on some seaside resorts on the French coast, notices the principal sea-bathing places lying between the mouths of the Seine and Orne, including Honfleur, Villerville, Trouville, Deauville, Villers-sur-Mer, Caen, and other places. The next paper is a lengthy one on some half hundred of the chief English and foreign health-resorts, in which detailed authoritative particulars respecting their climate, water-supply, health statistics, lodging accommodation, and general resources are given. Hints to travellers as to climate, exercise, and recreation, drinking, and food, and clothing; reviews of recent works cognate to the subject-matter of this serial; and a notice of some useful preparations for travellers, conclude the work. Altogether, it will be found that this publication, the

price of which is only one shilling, combines in a handy form a very large amount of information useful to the multitudinous seekers after health, who may be desirous of deciding with discretion where to take a holiday.

SANITARY JOTTINGS.

SANITARY.

NEW HOSPITAL FOR INFECTIOUS DISEASES AT SUNDERLAND. The Sunderland Town Council have agreed to purchase a site of land of about 12 acres in extent, at an estimated cost of 5,000*l.* for the purpose of erecting a hospital for infectious diseases. The site was chosen with strong approval from Dr Morley Douglas and the majority of the Health Committee, although an alternative site was offered at a much cheaper rate.

DR. A. J. MARTIN, in his pamphlet on the relation of Medical Science to Public Health (*le rôle du medecin en hygiène publique*) shows the necessity of a sanitary administration, and describes the sanitary organisation of every country in Europe except France.

THE inlet ventilation and warming of the new Church of St. Peter's, Limehouse, built by Mr. Ewan Christian, 11 Whitehall, for the Ecclesiastical Commissioners, has been undertaken by the Æolus Waterspray Company. The ventilating arrangements, so far as regards the extraction of the vitiated air, are simple enough, namely, three openings in the wood ceiling, protected with wood flaps, which can be raised or lowered at pleasure. These openings communicate with louvred openings in the gables. For the inlets and warming two Æolus Waterspray Ventilators of the Horseshoe pattern, furnished with heating stoves, are fixed in the vestibule. The stoves are coated with silicate cotton composition, and the whole apparatus is enclosed in ornamental wooden casing. The heating is effected by gas, which burns around a number of tubes in each stove, heating them to an intense degree, and through these the air, after being washed and purified, is passed into the Church. The gas fumes are carried off by a distinct flue. All that is seen inside the building are two circular openings, 16 inches in diameter, and 8 feet above the level of the floor; each instrument delivers 130,000 cubic feet per hour of purified fresh air, heated to a temperature of 140°; or 80,000 cubic feet of cold fresh air, at a temperature of 17° below the external temperature in the shade in summer time. The consumption of water in each instrument is 80 gallons per hour, and of gas 45 feet per hour. It is calculated that by means of these instruments the temperature of the Church in winter can be raised to 60° in less than two hours. The whole apparatus is perfectly under control, and can be stopped or set going at a moment's notice. The cost of applying this system is much below the ordinary charges for heating apparatus, and the working expenses nominal. The vestibule is to be used as a Sunday school-room, and to be partitioned off into class-rooms by curtains. The radiated heat from the stoves will suffice to warm this portion of the Church. At the eastern end of the south side aisle, in the organ chamber, the Æolus Company have fixed one of their very elegant ventilating gas stoves. These are in principle the same as those attached to the waterspray ventilators, but are minus the waterspray. The stove is connected at the base with the outer air by an opening through the wall. This can be used as an ordinary air inlet, cold in summer and warm in winter. Another of these stoves warms and supplies fresh air to the entry. The Æolus Waterspray Company are, we are informed, applying their system of ventilation to the composing room of the *Daily Telegraph*, the largest in London, and to the foundry, composing, printing rooms, and general offices of the new premises of the *Daily News*, Bowditch Street.

THE HOUSING OF THE POOR.

*'How best to help the slender store,
How mend the dwellings of the poor.'*

THE REV. S. A. BARNETT ON THE DWELLINGS QUESTION.—In his Annual Pastoral Address and Report for the year 1883-84, the Rev. S. A. Barnett, the vicar of St. Jude's, Whitechapel, thus speaks on this question:—Again, there is nothing but complaints to record as to the state of the dwellings. During the whole year acres of ground, cleared by the Metropolitan Board of Works so as to provide houses for the people, have remained barren as a desert. Some portion was put up to auction last summer and sold, but as yet there is no sign of building. Legal difficulties can hardly be the reason for delay, inasmuch as two large public-houses have been erected on the same site. Want of purchasers cannot either be urged, inasmuch as the East London Dwellings Company, of the formation of which I spoke last year, has been at all times ready to purchase. Because the Metropolitan Board of Works have other cares than the interests of the people, the hopes of the last ten years still remain only hopes, but some day there will be houses in which labourers may live under healthy conditions and friendly management, and there will be a common lodging-house where, as in a hotel, men may find a place in which to live and sleep free from the most degrading associations. The East London Dwellings Company, failing to get the site in Goulston Street, have bought a site at the back of the Royal Mint, on which houses for labourers will be erected, and where I hope the management will be entrusted to lady collectors. The houses include now St. George's House, a fine block which has been completed during the year, and which provides accommodation for thirty-eight families. The talk about the housing of the poor has given us neither facts nor light. That some of the poor live huddled in rooms which through neglect have become dirty, draughty, and rotten, has long been a recognised fact. That many poor families must live in single rooms is a necessity when society demands cheap luxuries, and the average wage is 1*l.* a week, irregularly paid. All that has been told has been long known, and no royal road to the remedy of evil has been discovered. Houses provided at reduced rents would reduce wages, and closer inspection would lead to more clever evasions. There is no remedy till the habits of the people are changed. The rich—be they landlords or employers—must regulate their occupations, and concern themselves in the well-being of their tenants and work-people. The rich must change their habits, they must give up their self-indulgence, before the poor give up their ways of riot and drunkenness. They must cease to worship sport before the plague of gambling can be stayed in the homes of the people. They must regard marriage differently if working women are to be mothers of pure men. The rich must change their habits, they must make friends among the poor—sharing and not only giving their good things—then the poor, too, will change their habits, and feel dirt to be intolerable, brutality to be degrading. Some such change goes on in the houses of this parish where the landladies are friends of the tenants, and where friendship has become the ladder up and down which the angels of kind thoughts and acts are ever passing.

NEW INDUSTRIAL DWELLINGS IN WATERLOO ROAD.—An extensive pile of new dwellings for the working classes, occupying an area of upwards of three-quarters of an acre, is now in course of erection in Waterloo Road, the owners and builders being Messrs. Quinn & Son, who have already erected similar buildings in Bethnal Green. The buildings, which consist of eight blocks, are quadrangular in form, seven of the blocks forming the quadrangle, with another block in the centre. Each block contains six floors, the dwellings on the different floors containing one, two, and three rooms, thus affording accommodation for single men as well as for families. The buildings are calculated to house a population of

850 persons. They are substantially erected in stock and red brick, with Portland cement windows, cornices, and dressings, cement also being used in the setting of the brickwork in place of ordinary mortar. A flat roof at the top of each block serves as a drying area as well as for recreation space for children. All the dwellings are fitted with cupboards, and each has separate sinks and coppers, with dust-shoots and water-closets on each floor. The dwellings are ventilated throughout from front to back, and each floor has separate ventilators at the different landings. There are likewise special ventilators in all the bedrooms, and all the soil-pipes are ventilated. The buildings are surrounded by four streets, with access from each, the principal approaches being from Waterloo Road on the east side and Duke Street on the west. Messrs. Borer & Dobbs, of London Wall, are the architects. The situation of the buildings renders them very convenient as residences for artisans employed in the locality. There are already numerous applications for tenancies. The erection of working men's dwellings by private enterprise is a practical outcome of the exposure of the want of proper accommodation for the working classes, and, in our opinion, the best solution of the insanitary dwellings question.

THE fortieth annual general meeting of the shareholders of the Metropolitan Association for Improving the Dwellings of the Industrious Classes has been held, under the presidency of the Hon. Dudley Fortescue. The report of the directors stated that the receipts on their various properties had been during the past year about 20,829*l.*, while the expenses were 8,590*l.* The population of the entire property of the association averaged 6,030. The profits of the year amounted to the sum of 9,220*l.* 8*s.* 7*d.*, and after meeting all expenses and repairs and usual charges, and providing for a dividend of 5 per cent. per annum, there remained a balance of 741*l.* 12*s.* 4*d.*, irrespective of 499*l.* 5*s.* 6*d.* already added to the guarantee fund, being the year's interest on the same; the sum of 1,190*l.* 17*s.* 10*d.*, therefore, represented the balance of the total profits of the year, of which 741*l.* 12*s.* 4*d.* remained.

MR. WYNTER BLYTH, who for some time past has been studying the sanitary aspect of the tenement streets in St. Marylebone, records in a recent report the result of an inspection of Carlisle Street. This thoroughfare, which is parallel with Edgware Road, contains 135 houses; and in no fewer than 113 there were found nuisances of a more or less severe nature, while in 41 the drains were so faulty in construction that they had to be relaid. The street contains a population of 1,406 inhabitants, nearly all of whom belong to the working class, and to a great extent each room accommodates a family. Notwithstanding this, the average amount of cubic space was very large (1,204 feet), larger than any of the tenements hitherto considered. During Mr. Blyth's period of office there has been a good deal of sickness in this street, a few cases of typhoid and much diarrhoea; but Mr. Blyth confidently anticipates that now the drainage has been so much improved there will be a corresponding improvement in the health of the inhabitants. The annual death-rate, as deduced from the records of seven years, represented nearly 22*o* per 1,000; but in this calculation no account could be taken of the deaths of the inhabitants that may have happened in various extra-parochial hospitals, so that the rate of mortality is somewhat understated. The largest number of deaths (66) was caused by pulmonary disease, other than phthisis, zymotic infections being fatal to 36 persons, and tubercular complaints to 33.

THE exhaustive report of Dr. F. W. Barry to the Local Government Board, on the general sanitary condition of Gateshead, with special reference to the prevalence of infectious diseases in the district, has been laid before the Commission inquiring into the state of the housing of the labouring classes. Dr. Barry says that there are probably

few, if any towns in the kingdom, in which so large a portion of the population are housed in tenement dwellings. Only one-fifth of the entire population self-contained houses; as to the remainder, two-fifths accommodation in flats, and the remaining two-fifths tenements or houses inhabited by more than one person. The report deals with all matters affecting the health of the inhabitants, in a comprehensive and elaborate manner, accompanied by interesting statistics. Referring to the fever he reports that 'in carrying out this inquiry I have nearly the whole of the houses in which cases of fever had been known to have occurred, and in this I became acquainted with many such examples of wretched housing as happily I have seldom met with elsewhere in order to remedy the unsanitary condition in which I find a large proportion of the tenemented property in Gateshead would appear desirable that the sanitary authority be invested with powers under section 90 of the Public Health Act, 1875, to make by laws for all houses not being or lodging-houses, which are let in lodgings or occupied by more than one family.' After giving credit to the authorities for all they have done, Dr. Barry says, 'the questions most needing attention are the improvement of the dwellings of the labouring poor, including the repression of overcrowding and the abolition of the noxious system of excrement disposal and the carrying out of comprehensive schemes of house deodorisation.'

ON the 28th ult. a large and influential meeting was held in Bishop Cosin's Library in the city of Durham under the presidency of the Bishop of the Diocese, to consider the question of the moral and sanitary condition of the dwellings of the poor, in the county of Durham. Bishop Cosin said that in his opinion the interest that has been excited on this question throughout the country should be allowed to pass away without leading up to some practical result. It appeared to him that the subject divided itself into two divisions making a better provision of dwellings for the lower classes by the erection of a class of houses, with improved sanitary arrangements, the provision of better dwellings by a strict enforcement of the laws already passed. The Rev. W. Moore, Rector of Gateshead, advocated the formation of Sanitary Aid Committees, which had done so much work in London and elsewhere. Mr. Austin, of Scotland, gave a graphic account of the sanitary defects of his town, the result of his personal inspection. The Bishop of Durham suggested the formation of philanthropic companies for the erection and improvement of dwellings for the poor, which, whilst being based on philanthropic motives, should be conducted on sound business principles. Dr. Barron, Medical Officer of Health for the County of Durham, expressed his opinion that the present law made ample provision for the evils complained of, but he thought that the formation of voluntary Sanitary Aid Committees would further strengthen the hands of the authorities. After an interesting discussion, it was ultimately decided to form a general Sanitary Aid Committee, or several of the leading gentlemen of the district, to be elected, with power to add to all parties, were elected, with power to add to the number.

AT the Brownhills Local Board meeting on Wednesday the 25th ult., two cases of overcrowding were reported. In one a father and mother and six children slept in one room, in the other a father and mother and seven children and one lodger slept in two small rooms.

MR. A. BURR, of Queen's Square, Bloomsbury, succeeded in obtaining the first premium in the open competition for artisans' dwellings, Battersea. Forty designs were submitted.

MUCH attention is being attracted in Scotland to the improved three-roomed workmen's houses now erected in Leith. Accommodation is provided for families instead of the thirty displaced, but the houses cover less ground than those they have superseded.

with range a portion of the basement has been appropriated as a coal-store, where, by arrangement with some actor, fuel will be kept on sale, at the lowest market for the convenience of such tenants as may choose, at times, to buy. The tenements, varying in size, provided each with a separate staircase; care having been taken in the case of the two largest blocks to have open balconies on every landing, with a view to thorough ventilation. It is in contemplation to have a store, where means will be taken for supplying, on terms, the miscellaneous wants of a community rather conveniently situated for access to shops and markets. A common benefit will be provided in the laying out a strip of land between the buildings and the river. There will also be a common club-room for the tenants. Rents will be from 10*l.* to 15*l.* a year.

PARKS AND OPEN SPACES.

*The law condemns both man and woman
If he steals the goose from off the common;
But lets the greater felon loose,
If he steals the common from the goose.*

OUT-DOOR SITTING-ROOMS.—On July 1 Princess (Marchioness of Lorne) performed the ceremony of opening the St. George's Burial-ground as a recreation ground. It is situated in Wakefield Street, and lies between Regent and Brunswick Squares, in the parish of St. Pancras. For a number of years it has been the centre for all kinds of refuse from an adjacent Irish street, and has been in a deplorable condition, in some cases the tombs falling in. The Kyrle Society, of which Miss Louise is the president, took the matter up, and now laid the ground out with shrubs and walks as a garden and place of recreation for the poor inhabitants of the district. At the opening ceremony Mr. Edward Ford, on behalf of the Kyrle Society, in an address, said that after four years' exertions they had succeeded in obtaining a faculty in laying out that garden, paying all expenses. In doing this they had received the hearty cooperation of the Rev. F. F. Goe and Mr. Gibb, the clerk of St. Pancras. Miss Aubrey had also, at an expense of 200*l.*, presented them with the fountain. They had tried very hard to get the neighbouring burial-ground, but had not yet succeeded.—On the representation of the Metropolitan Public Garden, Boulevard, and Playground Association, the Rev. R. Arbuthnot has thrown open the churchyard of St. James, Ratcliff, to the public for their free use and enjoyment as a recreation ground, the necessary seats having been presented by the association. It was owing to the action of this association that the disused burial-ground of St. Dunstan's, Finsbury, was opened to the public a short time since; they are about to throw open Spa Fields, Clerkenwell, and Ebury Square, Finsbury, to the public for their use and enjoyment.

ANOTHER PUBLIC GARDEN FOR NEWCASTLE.—On the 1st inst. the Mayor of Newcastle-on-Tyne opened the Ballast Hills Burial Ground, situate at Byker, Newcastle, as an ornamental garden for the use and benefit of the crowded industrial population of that district, which is intersected with many interesting historical associations. The Mayor (Dr. H. V. Newton), ever since he entered the Council, has been most energetic in his efforts to provide the inhabitants of Newcastle with public parks in various districts, and, after encountering much opposition, his labours lately have been crowned with great success. In the present case he was greatly aided by Mr. McIlvor Hensell, who at the opening of the place gave an interesting retrospective glance of the history of the city. His Worship the Mayor, also in a felicitous

speech, enjoined the inhabitants to strive individually to keep the ground in order and prevent the destruction of the beautiful shrubs and flowers with which it is adorned. He alluded to the expected opening of the Armstrong Park, one of the finest in this country, by the Prince of Wales, during his visit to Newcastle next month, and to the undeniable benefits of such open spaces in promoting the public health and happiness.

CREMATION NOTES.

THE *Sanitary Engineer* of New York states that the cremation of the body of the late Professor S. D. Gross, of Philadelphia, in accordance with his own directions to that effect, has had a tendency to increase the popularity of this mode of disposing of the dead. It has become so far the fashion in that part of the world that the proprietor of the crematory at Harrisburg announces that the demand for the services of his furnace is such that he can only undertake to supply it for the immediate vicinity.

CORRESPONDENCE.

[All communications must bear the signature of the writer, not necessarily for publication.]

THE SOUTH METROPOLITAN DAIRY.

Our attention has just been called by a subscriber to your journal to a notice you gave us in your May number, of our new undertaking, the South Metropolitan Dairy, Brixton, and we very much regret to find in it a paragraph that appears to cast a doubt upon a portion of our work, and that otherwise spoils a very favourable notice. After giving us credit for having based our 'operations upon the strictest sanitary principles,' you say—'We are not aware what is the system of sanitary inspection at the farms, nor the system of milk testing to prevent frauds by the employes at the farm and in London, nor how the health of farm servants and London carriers is secured—all essential points in the security of a milk supply.'

We are sure it was the intention of your reporter to do us justice at least, and had he put such questions to us as bear upon the above portion of the paragraph, we could have satisfied him, or the most fastidious mind on the points you have raised.

We beg to say that before we receive milk from any dairy farm, we always send down our inspector of farms who, after making a careful survey, reports to us; and unless the report is quite favourable we do not draw any milk from that farm. As to the milk testing, &c., samples of milk are taken before the carriers start, also on their return, and frequently at the point of delivery to the consumer as well as occasionally at the farms and on the railway stations. All and every churn is locked. As to the health of our servants, our medical officer visits them at their homes, and we are now about to house them under one roof. In a word we have endeavoured to keep faith with the public in the professions we have made, and to secure a really pure milk supply to the inhabitants of South London.

NASH STEPHENS & CO.

13 Grand Promenade, Brixton.

[It was not in the slightest degree our intention to cast any doubt upon the system of sanitary supervision acted on at the South Metropolitan Dairy. We simply declined to vouch for what we did not know, in so important a matter for the public health as milk supply. We are very glad to insert Messrs. Nash Stephens & Co.'s account of

the precautions taken by them for the protection of the public, in addition to the favourable opinions we have already expressed respecting their establishment.—ED.]

HAY AND HARVEST WORK WITHOUT BEER.

Farmers in considerable numbers have either given up, or are now giving up, the practice of giving their men beer in hay and harvest work. Conferences of farmers have recently been held in various parts of the country on this subject, and after full discussion it has been generally agreed that it was desirable to discontinue the practice of giving beer. At well-attended conferences of farmers in the Town Hall, Basingstoke, on June 11, and in the County Hall, Lewes, on June 17, the following resolution was unanimously passed:—

'That in the opinion of this Conference it is desirable in the interests of both masters and men that the practice of supplying beer in the hay and harvest field be discontinued, and that all work be paid for entirely in cash.'

All experience goes to prove that this change will be of great advantage to the men. They will soon fall into the way of providing themselves with good wholesome drinks at a small cost. Perhaps you will kindly assist by allowing the following receipts, that have been found useful, to appear in an early issue of your paper.

Home-Made Drinks for the Harvest.

STOKOS is a most refreshing and strengthening drink. It is easily made, and costs only 3d. per gallon.

Put into a large pan $\frac{1}{2}$ lb. of fine fresh oatmeal, 6 oz. of white sugar, half a lemon cut into small pieces. Mix with a little warm water, then pour a gallon of boiling water into it; stir all together thoroughly and use when cold. The lemon may be omitted, raspberry vinegar, citric acid, or any other flavouring may be used instead. More oatmeal may be used if preferred.

COKOS is a good nourishing drink made as follows:—8 oz. of sugar, 6 oz. of good fine oatmeal, 4 ozs. of cocoa at 10d. per lb., mixed gradually and smoothly into a gallon of boiling water; take to the field in a stone jar. Cost 6d. per gallon.

A GOOD HARVEST DRINK.—Boil $\frac{1}{2}$ oz. hops, $\frac{1}{2}$ oz. of ginger (bruised), in $\frac{1}{2}$ gall. of water, for twenty-five minutes, add 1 lb. of brown sugar and boil ten minutes more, then strain and bottle while hot; it will be ready for drinking when cold. It should be kept in a cool place. Dried horehound may be used instead of hops. Cost 3d. per gallon.

GINGER BEER.—Pour two gallons of boiling water over 1 lb. of lump sugar, 1 oz. of bruised ginger, two lemons sliced, let it stand till lukewarm, then add one tablespoonful of brewer's barm, or one small teaspoonful of baker's barm; let it stand twelve hours, then bottle it. It will be ready for use in twenty-four hours. Cost 4d. per gallon.

Boiling water poured on a few slices of lemon, with a little sugar, makes a very refreshing drink. Butter-milk should be more used as a drink.

One ounce of coffee and half an ounce of sugar in two quarts of water is a very thirst-quenching drink. So is cold tea, but neither of these is so supporting as the oatmeal drink.

It is quite a mistake to suppose that beer or spirits give strength. They do give a spurt to a man, but that quickly goes off; and spurts in hard heavy work, too often made, certainly lessen the working powers.

JOHN ABBEY,

Secretary of the Agricultural Department, C.E.T.S.

44 St. Giles, Oxford, June 30, 1884.

[The drinks recommended are excellent, but we cannot help thinking that the names are unfortunate. Imagine the expression of a haymaker or harvest hand when asked if he would take a glass of 'Stokos' or 'Cokos'!—ED.]

COMPETITIONS.

THE INTERNATIONAL HEALTH EXHIBITION.

THE Minister of Commerce, M. Hérisson, has nominated the following as members of the jury of the International Health Exhibition, now held at London. M. Arnould, Professor of Hygiene at the Medical Faculty of Lille, M. Bérard, Secretary to the Comité Consultatif of Art and Manufacture; M. Brouardel, Gueneau de Mussy and Proust; M. Buisson, Director of Elementary Education; M. Dethomas and Dr. Liouville, deputies; M. Dutert, Inspector of Schools of Design; Dr. Gariel, Assistant Professor of Physics at the Paris Medical Faculty; M. Guillaume, Member of the Institut; M. Guy, President of the Syndical Chamber of Wholesale Distillers of Paris; M. Jacquemart, Inspector General of Technical Education and of the Art and Trade Schools; M. Jartaud, President of the Paris Syndical Chamber of Wine and Spirits; M. Jordan, Professor of Art and Manufacture at the Ecole Centrale; M. Lavezzi, Principal Architect of the Berck-on-Sea Hospital; Dr. Layel, Professor of Hygiene at the Bordeaux Medical Faculty; M. Leblanc, Member of the Academy of Medicine, formerly Chief Veterinary Surgeon of the Prefecture of the Seine; M. Lesoufatché, architect; M. de Montmahon, Inspector-General of Elementary Education; M. Emile Müller, Professor of Art and Manufacture at the Ecole Centrale; Dr. Napias, General Secretary to the Society of Public Medicine and Professional Hygiene; M. Nourrit, Printer and Publisher; M. Schriber, President of the Syndical Chamber of India-rubber; M. G. Trelat, Professor at the Ecole Special d'Architecture; Dr. Vallin, Professor at the Military Medical School of the Val du Grace.

VENTILATION OPEN COMPETITION.

At the Ventilation Open Competition just concluded at Birke Messrs. Robert Boyle & Son, of 64 Holborn Viaduct and G.I. have been awarded the Gold Medal, the highest and only offered for their system of ventilation, it being adjudged the best.

NOTICES OF MEETINGS.

SOCIAL SCIENCE CONGRESS.

THE following 'special questions' relating to Sanitary Science been agreed upon between the local committees and the council Social Science Association for discussion in the Congress, to be in Birmingham in September next.

HEALTH.—1. What is the best method of dealing with (a) sewage; (b) the products of house and street scavenging; and products of combustion? 2. What are the best means, legisla- other, of securing those improvements in the dwellings of the which are essential to the welfare of the community. 3. H may the average death-rate of a population be considered an e test of its sanitary condition; and by what means can the high rate of children be reduced.

VACCINATION OFFICERS' ASSOCIATION.

THE next meeting of members of this Association will be Saturday, July 19, at 2.30 P.M., at the Charing Cross Hospital School, 62 Chandos Street, Strand, W.C.

AGENDA.—1. To read minutes of last meeting. 2. Correspondence. 3. Election of members and honorary members. 4. To take consideration a letter received from Dr. Henry Stevens, Inspector of the Local Government Board, asking for information from members of this Association, as follows: 'To show how promptly action of the Vaccination Officer the protection of vaccination secured to those in infected houses. Any instances in which prompt action has illustrated its advantages.' 5. To consider pamphlet issued by 'The National Health Society' upon the benefits of vaccination, and to move a resolution. 6. And such other business as may arise.

C. O. ELKERTON,
Hon. Sec.
20 Clarendon Street, Piccadilly,
London, S.

APPOINTMENTS UNDER THE PUBLIC HEALTH ACT.

MEDICAL OFFICERS OF HEALTH.

BRAUND, James Montague, M.R.C.S. Eng., L.S.A. Lond., has re-appointed Medical Officer of Health for the North I of the Stratton Rural Sanitary District, at £25 for one year.

CLERG, Walter, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Boston Port Sanitary District, at £50 for one year.

COGAN, Lee Fyson, L.R.C.P. Edin. and L.M., M.R.C.S. Eng., has been re-appointed Medical Officer of Health for the North Urban Sanitary District, at £150 per annum, for three years.

FISHER, Thomas, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Garstang Rural Sanitary District, at £50 for one year.

GAYLOR, Edward, L.R.C.P. Edin., and L.M., L.F.P.S. Glas., has been re-appointed Medical Officer of Health for the A Urban Sanitary District, at £40 for one year, and for the Urban Sanitary District at £20, for one year.

HOLLIS, Elphinstone, M.D., M.B., C.M., Univ. Edin., has appointed Medical Officer of Health for the Woodbridge Sanitary District, Suffolk, at £50 for one year, *vice* M. deceased.

JAMES, James Rowland, M.B. Univ. Edin., M.R.C.S. Eng., has re-appointed Medical Officer of Health for the Ystrad Urban Sanitary District, Glamorganshire at £150 per annum for one year.

LIVETT, Henry William, L.R.C.P. Edin., M.R.C.S. Eng., Lond., has been re-appointed Medical Officer of Health: Wells (Som.) Urban Sanitary District, at £30 per annum three years.

MARSHALL, William Norris, M.R.C.S. Eng., L.S.A. Lond., has re-appointed Medical Officer of Health for the Newent Sanitary District, at £40 for the year ending April 30, 188

MOXON, James Burdett, M.R.C.S. Eng., L.S.A. Lond., has re-appointed Medical Officer of Health for the Glanford Rural Sanitary District, at £120 per annum until June 30.

POLLARD, William Robert, L.R.C.P. Edin., L.R.C.S. Ire., has re-appointed Medical Officer of Health for the Blackburn Sanitary District, at £50 for one year.

ROBINSON, William, M.D., M.R.C.S. Eng., L.S.A. Lond., has appointed Medical Officer of Health for the Gateshead Sanitary District, at £350 per annum, as Medical Officer of Health, and £50 per annum for attending the hospital year to year, *vice* Green, resigned.

SEATON, Edward, M.D. Univ. Lond., M.R.C.P. Lond., has appointed Medical Officer of Health, Public Analyst, Examiner of Gas, for the Parish of St. Luke, Chelsea, per annum, *vice* Barclay, deceased.

William Henry, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Maryport Urban District, Cumberland, at £35 for one year, *vice* Pearson,

George Nicholson, L.R.C.P. Edin., M.R.C.S. Eng., has been appointed Medical Officer of Health for the No. 1 Division Wycombe Rural Sanitary District, at £40 for one year, *man*, resigned.

Nry Octavius, M.R.C.S. Eng., L.S.A. Lond., has been appointed Medical Officer of Health for the Cleckheaton Sanitary District, at £40 for one year.

William, M.B., C.M. Univ. Aberd., has been re-appointed Medical Officer of Health for the South Division of the Stratton Sanitary District, at £15 for one year.

George, L.R.C.P. Lond., M.R.C.S. Eng., S.S. Cert. Cantab., re-appointed Medical Officer of Health for the Bishop-ly, Buntingford, Hertford, and Ware Rural, and the Hertford, Hertford, and Ware Urban Sanitary Districts at £600 per annum, for five years.

Thomas, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the No. 2 Division of the Rural Sanitary District, at £35 for one year.

S., CLERKS TO GUARDIANS, INSPECTORS OF NUISANCES, &c.

Mr. James has been appointed Inspector of Nuisances for the Scarborough Urban Sanitary District, at £105 per annum, *lay*, resigned.

Mr. John Jacob, has been appointed Public Analyst for the Borough of Penryn, *vice* Parry.

Joseph, has been appointed Surveyor to the Shildon and Hackley Local Board and Urban Sanitary Authority, at £45 per annum, and Inspector of Nuisances at £600 per annum, *vice* Laycock, appointed Surveyor to the Walker Local Board and Urban Sanitary Authority.

Frederick, has been appointed Inspector of Nuisances for the Wareham Urban Sanitary District, at £10 per annum, *bb*s, resigned.

Mr. Thomas, Branch Manager of the London and Provincial Banking Company, has been appointed Treasurer to the Local Board and Urban Sanitary Authority, and to the City Guardians and Rural Sanitary Authority, Monmouthshire Green, resigned.

John, has been appointed Surveyor and Inspector of Nuisances to the Corporation and Urban Sanitary Authority of Wycombe, Bucks, at £150 per annum, *vice* Wakelam, declined the appointment.

Mr. Herbert Edward, Manager of the Chipping Sodbury of the National Provincial Bank of England, has been appointed Treasurer to the Chipping Sodbury Guardians and Sanitary Authority, *vice* Foxwell, resigned.

George I. C., C.E., has been appointed Surveyor and Inspector of Nuisances to the Corporation and Urban Sanitary Authority of St. Helens, at £400 per annum, *vice* Hart, resigned.

Thomas, has been appointed Inspector of Nuisances for the Leighton Buzzard Rural Sanitary District, at £83 per annum, *vice* Mr. W. Brown, deceased.

B., has been elected Chairman of the Bilston Improvement Commissioners and Urban Sanitary Authority for the year.

Mr. Christopher Lethbridge, Solicitor, has been appointed to the Launceston Local Board and Urban Sanitary Authority, at thirty guineas per annum, *vice* Mr. J. L. Coward, resigned.

Mr. F. has been appointed Collector to the Awe Local Board and Urban Sanitary Authority, Gloucestershire, at £15 per annum.

Mr. John, has been re-appointed Inspector of Nuisances for the Glanford Brigg Rural Sanitary District, at £100 per annum and Surveyor at £10 per annum, until June 30, 1886.

Mr. G. E., has been appointed Collector to the Corporation and Urban Sanitary Authority of Blackburn at £120 per annum.

Mr. Thomas, has been appointed Accountant to the Corporation and Urban Sanitary Authority of Bradford, Yorkshire, per annum.

Mr. Francis Joseph, Solicitor, has been appointed to the Reeth Guardians and Rural Sanitary Authority, at £40 per annum, as Clerk to the Guardians, and as Clerk to the Rural Sanitary Authority, to the Attendance Committee, and to the Assessment Committee, to be fixed from time to time, and fees as Returning Officer per annum; Registrar of Births, &c., *vice* Tomlin, *d*.

Mr. Christopher, on being relieved of his duties as Inspector of Nuisances, is to be continued as Surveyor to the Rough Local Board and Urban Sanitary Authority, at £200 per annum, and £25 per annum for the Water Works.

Mr. Thomas, has been appointed Collector to the Westwood Improvement Commissioners and Urban Sanitary Authority, at £125 per annum, *vice* Downey, appointed *tant*.

Mr. John, has been elected a Member of the Dronfield Local Board and Urban Sanitary Authority, *vice* Rhodes, *d*.

Mr. Samuel, has been re-appointed Inspector of Nuisances for the Whitwick Urban Sanitary District at £10 per annum, for the year ending June 24, 1889.

Hill, Mr. F. A. Brooks, Bank Manager, has been appointed Treasurer to the Pewsey Guardians and Rural Sanitary Authority, *vice* Wood, resigned.

HOLDROYD, Mr. Alfred, has been re-appointed Inspector of Nuisances for the Cleckheaton Urban Sanitary District, at £30 for the year ending June 24 next.

HOOLEY, Mr. Cosmo C., has been appointed Surveyor to the Barton-upon-Irwell Rural Sanitary Authority, at £225 per annum, *vice* Price, resigned.

HOULDERSHAW, Mr. William, has been appointed Inspector of Nuisances for the Liversedge Urban Sanitary District, Yorkshire, at £26 per annum, *vice* Womersley, whose appointment has expired.

HUGHES, Mr. Thomas, has been appointed Public Analyst for the Borough of Newport, Mon., until Sept. 11.

JONES, Mr. E. W. T., has been re-appointed Public Analyst for the Borough of Walsall for one year.

KNIGHTS, Mr. James West, has been re-appointed Public Analyst for the County of Huntingdon.

MANN, Mr. Robert, has been elected a Member of the Handsworth Local Board and Urban Sanitary Authority, *vice* Bragge, deceased.

MCNEILL, John Patrick, M.D. Univ. Dub., has been re-appointed Public Analyst for the Borough of Tiverton.

NIXON, Mr. Thomas, has been re-appointed Inspector of Nuisances for the Stafford Rural Sanitary District, at £50 per annum, in addition to £75 and £35 per annum, as Inquiry and Attendance Officer to the School Attendance Committee.

PLATT, Mr. Samuel, has been appointed Inspector of Nuisances for the Gainsborough Urban Sanitary District, at £30 per annum, *vice* Greenhalgh, relieved of his duties (but continued as Surveyor).

PONTING, Mr. Frederick William, Banker, has been appointed Treasurer to the Preston Guardians and Rural Sanitary Authority, *vice* Dalby, resigned.

PRICE, Mr. John, C.E., Assoc. M. Inst. C.E., M.S.E., has been appointed Surveyor and Inspector of Nuisances to the Toxteth Park Local Board and Urban Sanitary Authority, at £350 per annum, *vice* Hall, deceased.

RIDLINGTON, Mr. Walter, has been appointed Surveyor, Inspector of Nuisances, and Collector to the Holbeach Local Board and Urban Sanitary Authority, at £100 per annum, *vice* Douse, resigned, after nearly twenty-two years' service.

RILEY, Mr. Thomas, has been elected a Member of the Board of Fleetwood Commissioners and Urban Sanitary Authority, *vice* Warbrick, deceased.

ROBINSON, Mr. Thomas, has been elected a Member of the Nelson Local Board and Urban Sanitary Authority, *vice* Elliott, resigned.

SHAW, Mr. Joseph, has been appointed Surveyor to the Stainland-with-Old Lindley Local Board and Urban Sanitary Authority at £15 per annum and re-appointed Inspector of Nuisances at £30 per annum for three years, from April 11 last, and Collector at £10 per annum (£65 altogether).

SMALLPIECE, Mr. Gilbert John, has been appointed Treasurer to the Guildford Guardians and Rural Sanitary Authority, *vice* Haydon, resigned.

STAINTHORPE, Mr. Thomas William, has been appointed Surveyor and Inspector of Nuisances to the newly-formed Eston Local Board and Urban Sanitary Authority, at £150 per annum, for three years, from July 1.

STEPHENSON, Mr. John, has been re-appointed Inspector of Nuisances for the Boston Port Sanitary District for one year.

STUART, Mr. Charles Madock, has been appointed Public Analyst for the Borough of Newcastle-under-Lyme, *vice* Purdie, resigned.

THORPE, Mr. G. A., has been appointed Deputy Accountant to the Corporation and Urban Sanitary Authority of Bradford, Yorkshire, at £200 per annum.

UNWIN, Mr. W. T., has been appointed Surveyor and Inspector of Nuisances to the March Local Board and Urban Sanitary Authority, at £80 per annum, *vice* Amos.

WAKELAM, Mr. Henry Titus, C.E., who was appointed Surveyor and Inspector of Nuisances to the Corporation and Urban Sanitary Authority of Chepping Wycombe, Bucks, has declined the appointment, and continues as Surveyor and Inspector of Nuisances to the Corporation and Urban Sanitary Authority of Oswestry, at the increased salary of £150 per annum.

WHITTAKER, Mr. John, has been appointed Surveyor, Inspector of Nuisances, and Collector to the Worsborough Local Board and Urban Sanitary Authority, Yorkshire, at £140 per annum, with house, gas, and water, *vice* Senior and Wilkinson, resigned.

WILLIAMS, Mr. Frederick Edward, has been appointed Clerk to the Leigh Guardians and Rural Sanitary Authority, Lancashire, at £120 per annum as Clerk to the Guardians, £60 per annum as Clerk to the Rural Sanitary Authority, £30 per annum as Clerk to the Assessment Committee, £20 per annum as Clerk to the School Attendance Committee, and fees as Returning Officer and Superintendent Registrar of Births, &c., *vice* Heywood, resigned.

VACANCIES.

MEDICAL OFFICER OF HEALTH for the Nottingham Urban Sanitary District.

MEDICAL OFFICER OF HEALTH for the Cork Urban Sanitary District.

MEDICAL OFFICER OF HEALTH for the Whitby Urban Sanitary District.

MEDICAL OFFICER OF HEALTH for the No. 1 or Whitby Division of the Whitby Rural Sanitary District.

MEDICAL OFFICER OF HEALTH for the George Urban Sanitary District, Lancashire.

CLERK to the Onslow Guardians and Rural Sanitary Authority. In view to the Seaton and Pendlebury Local Board, Lancashire. **SEVENTH AND INSPECTOR OF NUISANCES** to the Haverhill Local Board and Urban Sanitary Authority. £100 per annum, from year to year, with the prospect of additional salary as Manager of the Gas Works. Application, sent inst., to Charles F. Freeman, Clerk, Haverhill, Suffolk.

SANITARY INSPECTOR for the Parish of St. Pancras, £50 rising to £70 per annum. Application, 17th instant, to Thomas Eccleston Gilb, Veterinary Clerk, Pancras Road.

LOCAL INTELLIGENCE.

The Stoke Damour Rural Sanitary Authority and their officers have subscribed for a tablet in memory of their late chairman, Mr. F. C. Rickard which has been placed in the Board room. It consists of a slab of coloured stone, on which is placed a white marble scroll, bearing the following inscription:—'This tablet is erected by the Commissioners of the Poor of Devonport and their officers in remembrance of the late Francis C. Rickard, Esq., who for twenty-six years was a member of the Board, and for the last fourteen years faithfully carried out the duties of Chairman. April 1884.'

The Cambridge Improvement Commissioners and Urban Sanitary Authority have passed the following resolution by 17 yeas to 10:—'That it is expedient to apply in the next session of Parliament for legislative sanction to alter the constitution of the Board of Commissioners, and to amend the provisions of the Local Acts and the Award Act with respect to the relations between the authority and the town on the basis of the provisions of the Bill of 1874 and empowered the Parliamentary Committee to take the necessary steps for carrying it into effect.'

The Denon Local Government District is to be merged in the Moughton District, on Sept. 29, by Provisional Order of the Local Government Board.

The Barking Town Local Board and Urban Sanitary Authority have increased the salary of the Surveyor from £25 to £30 per annum, and that of the Inspector of Nuisances from £40 to £50 per annum.

The Maryport Urban Sanitary Authority, upon a vacancy for a Medical Officer of Health having arisen by the resignation of Dr. Pearson, have increased the salary from £25 to £30 per annum.

At Llandyfaula, a statutory meeting of owners and ratepayers was held some time since, and a resolution passed, that it was expedient that it should be constituted a Local Government District. An inquiry was then held in accordance with the Act of Parliament but as certain works of drainage, &c., had not been carried out, the Inspector declined to report in favour of the resolution. They have now, however, been completed, and another inquiry held, at which the Inspector intimated that he would report in favour of the parish being constituted a Local Government District under the title of 'The Monas Bridge Local Government District,' with a Board of nine members, Mr. H. Bulkeley Pryce to be the returning officer.

The parish of East Grinstead has been constituted a Local Government District by Provisional Order of the Local Government Board. There are to be twelve members, and, if there should be a contest, the voting papers are to be collected on August 20.

The St. Anne-on-the-Sea Medical Officer of Health commences his report to the Local Board and Urban Sanitary Authority, dated July 1, with the following satisfactory sentence:—'During the past month not a single death has taken place in this district.'

The Bedford Rural Sanitary Authority, at their meeting on June 21, reconsidered the proposed reduction of the salary of Dr. George Reid the Medical Officer of Health, from £75 to £50 per annum, in compliance with the request of the Local Government Board (see page 576) and, after a short discussion, a resolution that a reply be sent to the Local Government Board to the effect 'that the authority could not come to any other conclusion than that previously arrived at,' was proposed and carried by 11 yeas to 3.

The Colchester Town Council and Urban Sanitary Authority, have voted Two hundred guineas to Mr. Charles Clegg, the Surveyor, in recognition of his extra services in connection with the erection of a water tower, &c., instead of increasing his salary £50 per annum, which he had asked for.

CREDITON IMPROVEMENT COMMISSIONERS AND URBAN SANITARY AUTHORITY. At the annual election on the 1st instant, the following were elected commissioners for the ensuing three years, viz.—Messrs. James Tompkinson, *John Squire, William Pope, *G. H. Chaplin, *W. H. Symon, William Daxbridge, *James Bockle, *G. Dickson, *William Lohout, and *A. A. Cole. (* Retiring commissioners re-elected).

VACCINATION OFFICERS' ASSOCIATION.

This association was inaugurated on Feb. 16, 1884, and has already on its roll of members almost every vaccination officer of the metropolis and surrounding districts, and as honorary members a large number of public vaccinators, medical officers of health, and other distinguished persons interested in the promotion of vaccination. The association has received the cordial support of Henry Stevens, Esq., M.D., one of Her Majesty's Inspectors under the Local Government Board, who, under date Jan. 31, 1884, wrote to the promoters of the association as follows:—'I may state that I fully sympathize with you in your desire to unite together for mutual support and co-operation, and I believe that much advantage might accrue to the community by securing a more complete administration of the Vaccination Acts through such combination. The objects of the association are to secure as far as possible uniformity of action in working of the

Vaccination Acts, the exchange of experience and advice, mutual benefits of its members. The members of the association consider and answer all matters of correspondence submitted for consideration, and will, to the best of their ability and against all brother officers in any matters of interest arise out of their duties. The association will further endeavour to obtain such alterations in matters of detail as from time to time in their opinion prove beneficial to the cause they represent. vaccination officer, public vaccinator, and medical officer is in cognizance of the many difficulties and hindrances that are met with in the proper enforcement of vaccination, which, if carried out and properly enforced, has repeatedly proved to be incalculable benefit to the community, and the association by thorough combination and with the hearty support and aid of the medical profession generally, and others interested in the promotion of efficient vaccination, the objects of the Vaccination will be better served in the future and the public health improved thoroughly. The association do not confine themselves to London and districts only, therefore the support of all officers, public vaccinators, and medical officers of health in the country is earnestly desired, and the association appeal to gentlemen to become members and honorary members. The subscription for members (vaccination officers) is 5s., and for members 10s. The association is under the management elected officers and committee, consisting of twelve who are subject to annual election at the general meeting in February. Annual balance sheet and report will be published. Application for membership, honorary membership, rules, and all other information can be obtained of the honorary secretary, Charles O. Ell, Clarendon Street, Piccadilly, S.W.

MANAGEMENT.

Chairman.—Mr. Charles Shattuck, St. Mary Abchurch, E.C. **Vice-Chairman.**—Mr. William M. S. Sherman, Whitechapel, W. **Treasurer.**—Mr. John H. Richards, St. Pancras.

Honorary Secretary.—Mr. Charles O. Ellerton, St. Hansbury Square.

Committee.—Mr. Charles Arkhine, vaccination officer, Leamington; Mr. William Bence, vaccination officer, Edmonstone; Mr. C. Eltherton, vaccination officer, St. George's, Uxbridge; Mr. Charles Henson, vaccination officer, Lambeth; Mr. William H. Henson, vaccination officer, Islington; Mr. Thomas W. Masken, vaccination officer, Greenwich; Mr. J. R. Moynier, vaccination officer, Mr. John H. Richards, vaccination officer, St. Pancras; Mr. Shattuck, vaccination officer, Kensington; Mr. William H. Henson, vaccination officer, Whitechapel; Mr. William John vaccination officer, Mile End Old Town; Mr. William H. Henson, vaccination officer, Bethnal Green.

Honorary Members.—Lieut. General Batten, 14 North Square, Kensington, W.; Dr. Charles Thomas Blackman, 41 Grove N.; Dr. W. Piddell Branson, 41 Kewdale, Sydenham; Dr. Edwin Child, Kingston-on-Thames; Dr. C. C. Claverie, Brooklands House, Homestead Road, N.W.; Dr. Robert (Thomas's Hospital); Dr. Richard Fegan, Westcombe Park, South, S.E.; Dr. Charles Maynard Frost, 97 Ledebur, Notting Hill, W.; Dr. William Hall, Tottenham, Middlesex; Henry F. E. Harrison, 31 Shepherd's Bush Grove, W.; Dr. Leane, 1 Duck Street, Whitechapel, E.; Mr. Shirley F., St. Pancras; Dr. Robert S. Nightingale, 688 Commercial Linehouse, E.; Dr. John Reid, 12 Bridge Avenue, Hagen W.; Dr. George A. Rogers, 164 High Street, Shadwell; Thomas Scoresby-Jackson, 'St. Hilda,' Hoe Street, Waltham; Dr. James Smart, 256 Cambridge Road, E.; Dr. Townsend, 27 Upper Phillimore Place, Kensington, W.; Dr. G. Wells, Beaumont Terrace, West Kensington, W.

NOTES AND QUERIES.

Having for some time back been in the receipt of queries relating strictly to sanitary work, and which it would be easy to answer without having to refer our correspondents to competent professional advisers, we have opened a column in which to register such queries. Replies thereto as can fairly be expected from us, and our readers are invited to make such use of this column as to benefit themselves and the community. Both queries and replies, however, be subjected, if unnecessarily long, to a strict edit.

105. FLOWERS IN SICK ROOMS.

Are cut flowers unhealthy in a sick room? Are flowers in pots unhealthy in a bedroom either during the day or night?

[Healthy plants and cut flowers are not unwholesome in other inhabited rooms, and in those cases where mischief from their presence, it is invariably caused by fungigenous state, unventilated earth of the pots or in the garden which cut flowers are kept. To secure immunity from any effects the water of cut flowers must be frequently changed, the potted plants be effectually drained, and have the soil stirred up from time to time. Interesting papers on this may be consulted by reference to the *Lancet*, Vol. L, 1884, the *Practitioner*, Vol. II, 1884, p. 307, and Vol. L, 1884, and also to the *British Medical Journal*, Vol. L, 1884, —Ed.]

ORIGINAL PAPERS.

NOTIFICATION OF INFECTIOUS DISEASE: ITS IMPORTANCE AND DIFFICULTIES.*

By ALFRED HILL, M.D.,

Medical Officer of Health for Birmingham.

THE Lord Bacon did or did not say that 'knowledge is power' matters little compared with the importance of the truth expressed in the dictum. A knowledge of the causes, symptoms, and extent of a disease, we should possess very little to alleviate or cure it; but without a knowledge of its existence, none at all.

In order to prevent the spread of disease, and the possibility of one or two cases developing into a rapid and fatal epidemic, a knowledge of the occurrence of first cases is indispensable. The importance of this knowledge, I presume, will be universally admitted. There is only one way of acquiring such knowledge, and that is by means of notification, the imparting of it or making it known to the proper person or authority.

Coming out of the small section who deny the utility of notification at all as too insignificant to demand attention, there are two classes of people who agree that notification is desirable, but stand in opposition to each other as to the person on whom should the duty of notifying devolve. This question is one not so much exercising the mind of the general public as that of the members of the medical profession, but it is one upon which, in this account, it is very desirable there should be as nearly as possible unanimity of opinion and action among medical men, as it is upon them and them alone that primarily the duty of notification of some kind must rest, and without co-operation any notification of a thoroughly efficient kind is impossible. There is a difficulty, however, in obtaining this unanimity, and while one member of the profession fully admits the importance and necessity of notification, and is willing to do it, another, and, I believe, a smaller and diminishing one, strenuously resists all attempts to impose the duty upon them, maintaining that it should be imposed solely on the householder or guardian. At first sight there is a certain amount of reasonableness in this view of the case, but even when it appears that its advocates proceed to argue that notification is in operation it has had the effect of doing harm rather than good. If this is the case, instead of declaring that they are in favour of early notification as an abstract proposition, they should, to be logical, declare themselves against it, unless they are prepared to prove that notification by the householder is beneficial, while notification by medical men it is injurious.

We are here to consider the alleged objections to compulsory notification by the medical attendant, and those which constitute the chief obstacles to its adoption, with which notification has to contend. The chief of these is the compulsory character of the compulsion pure and simple, no objection being made to the proposal to put compulsion

on the householder or guardian, though I fail to see that compulsion as such need be considered more objectionable by a professional than by a non-professional informant. It is, however, said to be derogatory to a medical man's dignity and self-respect to be so compelled. But wherever a duty of great importance to the general welfare has to be performed, the only way to ensure its performance is to make it compulsory; to make the Act simply permissive would inevitably mean failure from non-compliance on the part of some, where it is essential that compliance should be made by all. It is rather late in the day for medical men to display such extreme sensitiveness on this point, and to treat it as though it were a new principle and practice. They are accustomed to notify under compulsion the deaths of persons whom they have attended; and although it is true that when this measure was originally proposed it met with similar opposition to that now exhibited to the notification of disease, it became law; and while it proves a great public advantage, it is found to be in no way detrimental to the interests of the medical man, or hurtful to his *amour propre*. Compulsion again is seen in the laws in respect of registration of medical men, and of their services as scientific witnesses, in respect of the sale of poisons, and more heavily still with regard to the provisions for the practice of vivisection. Under these circumstances, it seems difficult to understand why, when another service inseparably connected with professional duty, and inferior to none of the others in importance, is required in the interests of public health, there should be such a violent opposition to its imposition. It seems to me that the dignity of medical men, instead of being injured by the performance of the duty required, would be greatly magnified and enhanced. All law is associated with compulsion, which is as indispensable to control the action of non-medical men as of medical. This is seen in the registration of births, vaccination, education, regulation of hours of labour in mills, manufactories, and other places, service on juries, and numerous other matters, and it is only because it is impossible to accomplish the object in view by voluntary action that penalties become necessary. It has been urged by one opponent of compulsory notification that the voluntary principle is the true one, that it has been known to succeed, and he does not see why it should not be adopted everywhere. There is a simplicity about this view which renders any serious consideration of it unnecessary.

No one will deny, I presume, the value for various purposes of the certification by the medical man of cases after death, but it is of little use as regards the prevention of disease, because it comes too late; notification seeks to remedy this defect by giving to the sanitary authority the earliest information possible of the case, by which not only may the best be done for it in the way of removing causes, and rendering assistance in various ways, so as probably to prevent a fatal termination, but also to prevent the spread of the disease to other members of the household and to neighbours. The causes of the disease are often not inquired into by the medical attendant, who is apt to regard his duties more as curative than preventive; it is seldom that he makes a searching examination of a house with the view of discovering sanitary defects, whereas the duty of a medical officer of health is not to meddle in any way with a patient, but to seek for any existing defect in the sanitary arrangements of the dwelling. Let us

*Read at the Conference organised at the International Sanitation by the Society of Medical Officers of Health, the Sanitary Institute of Great Britain, and the Parkes Museum of Hygiene, June 13, 1884.

take a common case; a member of a family may be suffering from diphtheria or typhoid fever, which the medical attendant may skillfully diagnose and treat, but he may content himself with some general inquiry as to the sanitary condition of the house and its surroundings without making a rigorous investigation; the cause of the illness may be probably a sink or cellar drain in direct communication with the sewer, or it may be a faulty water-closet, leaky soil pipe, a polluted well, or some similar defect, discoverable only by such an investigation as would be made by the medical officer of health. If this exciting cause of the illness be allowed to remain during the illness, there is little likelihood that the patient will recover, but if speedily removed the probabilities of recovery are immensely enhanced, *causa sublata tollitur effectus*. So that not only is the recovery of the patient rendered more likely, but the dangers of the spread of the disease are likewise diminished. This illustration will serve to indicate the value of early notification, and one of the directions in which it is calculated to be of advantage.

The objection to voluntary notification is that it is incomplete, and, as human nature is constituted, probably ever must be, but unless complete it is useless for the prevention of epidemics; it is only because of its incompleteness, and, therefore, uselessness under the voluntary system, that it is necessary to resort to compulsion. The value of complete notification was well seen in Birmingham during the early days of the present visitation of small-pox. This disease is one which from its rarity, and from the dread of it in the minds of the public, is more likely to be spontaneously notified than any other ordinary zymotic; the consequence was that for many months the disease could get no footing in the town, because under the influence of fear every case was notified to me directly on its nature being made out; over many months seventy-seven sporadic cases were reported, with the result that the disease was prevented spreading by means of isolation, disinfection, &c.; but in time cases occurred which were not reported, and then the disease, liberated from control, rapidly became epidemic; as long as every case was reported the epidemic was prevented, but no longer. The voluntary system answered for a time, but soon broke down as it always will do, and as it always has done from time immemorial to the present. The experiment has been made so long that it is unnecessary to continue it; it has indeed lasted too long, and to continue it still is altogether unjustifiable. Of the three hundred practitioners in Birmingham only one hundred and eighteen have ever voluntarily notified.*

* In reference to this statement, Mr. Lawson Tait, F.R.C.S., wrote to a daily contemporary:—"The experiment has been conducted by the Health Committee, of which I am chairman, and I am not aware that they have expressed any opinion whatever to the effect that it is a failure. Personally I regard it as a success, and the fact that nearly 2,400 cases were reported last year is sufficient evidence in support of my belief. In 1877, before the experiment began, we admitted only 43 cases of scarlet fever to the hospital, while last year we admitted 638, a number much larger than we had satisfactory accommodation for. The Town Council has just sanctioned an expenditure of 28,000*l.* for a new hospital for scarlet fever, and last year they distinctly refused to apply for powers to secure compulsory notification in the Consolidation Act. We believe, therefore, that compulsion is wholly unnecessary. There are only 257 practitioners in the 'Medical Directory' returned as practising in Birmingham, and of these I believe there are only 140 practising in such a way as to be likely to be called upon to deal with infectious diseases within the municipal area. As Dr. Hill tells us 118 have notified voluntarily, we may take it that there are only some 22 whom we have yet to convert to our views."

The voluntary system answers very well in the case of cholera, because so great is the alarm and even horror excited by the disease, that it is practically compulsory, in other words, that result is effected by fear which is denied by reason. But in the case of a disease of which there is no fear, such as scarlet fever, although it is a thousand times more destructive to life, the voluntary system breaks down altogether. Instead of the medical man reporting every case of preventable disease, he reports only such as he chooses; he will report for instance the case of a domestic servant whose presence in a large and respectable family is considered objectionable, and whose removal is therefore desired, and she is removed to the hospital accordingly, but the next case he may for special but insufficient reasons decline to notify, although the danger to the public may be as great in the one case as in the other.

There is generally no reticence in publishing to the whole world the illnesses of Royal or distinguished personages, and in much more detail than is required for the protection of the public health, while in notification of disease to the sanitary authority there is no publication at all, there is simply intimation accepted in confidence and acted upon with the sole view of benefiting the patient and the community. Notification to be of real value must not be optional but imperative, it must not be sub-ordinated to individual interests or caprice, because it is then too uncertain, too impartial, and frequently too late. As a fact I frequently receive from the medical man notification of cases of zymotic disease after being attended by him for several weeks, and sometimes after the death of the patient. This is under the voluntary system which obtains in Birmingham, although for such information a fee of five shillings is paid. To expect efficient, that is, complete notification by voluntary means, is to ignore all past experience, and to display a credulity which would discredit an intelligent child.

Another alleged objection to notification by the medical man is that it leads to the concealment of cases, and consequent spread of disease, but the proof of this has never been forthcoming, and the objection rests on mere assumption. Let us hear on the contrary what is said by some who have had experience of the actual working of the compulsory clauses, for a little practice is worth much hypothesis, however ingenious. Dr. Butterfield, when Medical Officer of Health of Bradford, wrote, 'As to the allegation that people would conceal infectious disease, and not send for medical advice for fear of having the case reported, I can safely say that such has not been the case in this town.' The Mayor of Macclesfield says, 'Our experience is that compulsory notice does not tend to concealment, but rather the reverse.' The Mayor of Oldham gives similar testimony, and the same with other towns; while in Dundee it was found that there was less concealment of disease after notification was made by the medical attendant, than there had been previously when the duty rested with the householder. It thus appears that there is no ground for the assumption of notification leading to concealment, and if there were, it would constitute an argument against notification, whether by the householder or the medical man, and is therefore an argument against notification altogether.

It is further asserted that compulsory powers promote antagonism between the medical practitioners

and the medical officer of health. If this be so, I am bound to say that I have failed to find evidence of it worthy of the name; it might be possible by diligent inquiry to discover a solitary case of the kind; but 'one swallow does not make a summer,' and it has happened more than once that conflict of opinion and antagonism have arisen between even practitioners themselves on other questions than that of notification. For many years in Birmingham there has been voluntary notification, but in no single instance has any antagonism, or even unpleasantness arisen between the medical men and myself. Abundant testimony to the same effect is afforded in towns where the notification is compulsory; thus at Leicester, Alderman Windley stated that 'All fear of collision between the medical officer of health and the profession had died out, and the certificates were sent in without difficulty;' at Bradford Dr. Butterfield reports, 'I know of no medical man who is opposed to the working of the Act.' The Mayor of Oldham states 'that there has been no unpleasantness with the medical profession in putting the clauses into effect; they have as a body willingly co-operated with the medical officer of health;' and from Llandudno we hear that 'to the credit of all our medical men, they work most harmoniously with the board.' After the unvarying testimony of such a cloud of witnesses there seems to be no ground for alleging antagonism, with which it would seem that opposition has possibly been confounded.

If such antagonism were found to exist between the medical profession and the medical officer of health, 'twere a grievous fault,' and it would be necessary to discover the causes of it, and remove them, because no good is to be expected without the cordial co-operation of the medical profession with the sanitary authority.

It has been alleged that the conduct of the medical officer of health is likely to be inquisitorial, and that he may interfere with the patient, and otherwise take advantage of his opportunities to annoy and injure the practitioner. This contingency is so remote and improbable that it is scarcely worthy of serious discussion. No medical officer of health properly qualified for his duties could act in such a manner; to suppose otherwise would be to assume that the moment a medical practitioner becomes a medical officer of health he forgets professional obligations, and loses the instincts of a gentleman, which is not only absurd, but opposed to experience.

There have been doleful predictions that notification by medical men would be a betrayal and destruction of that confidence which is necessary between doctor and patient; such would no doubt be the case in some instances if there were no compulsory law requiring it, if the secrets of the sick room were published, instead of the case being simply notified, if the object were to injure instead of benefit the patient and the community, and if all medical men were not placed under the same necessity to notify; when further, it is the rule for the householder, as well as the doctor, to notify, the former can have no possible ground of complaint in this direction. Here is seen one of the advantages of the dual system. It was attempted by Mr. Ernest Hart in his 'model clause' to meet this question of betrayal of confidence, and at the same time the objection of medical men to be put under a penalty, and, in order to do this, he proposed that compulsory

notification should be put upon the householder, to whom the medical attendant must furnish a certificate, which the householder is bound by penalty to forward to the sanitary authority, while no penalty falls upon the medical attendant in the event of his refusal to certify. The weak point of this clause is that it is impossible to obtain the co-operation of all medical men without the imposition of a penalty, so that this objectionable regulation is really rendered necessary by the fault of the medical profession itself, which, therefore, cannot reasonably complain. *Salus populi suprema est lex.*

It is a remarkable fact that out of thirty-eight towns in Great Britain which have availed themselves of compulsory notification thirty-four have adopted the system of direct notification by the medical attendant, while thirty of these require notification also by the occupier. In three of them only does it rest with the medical man to notify indirectly or to the occupier, so that the dual system is found to be by far the most in favour: it is the one recommended by the Local Government Board in 1878, and by the Select Committee of the House of Commons in 1882; it is theoretically the only efficient one, and in practice it has been proved to work satisfactorily. It is the system embodied by Mr. Hastings in his Bill of 1883; and it is, I believe, the one which commends itself to all impartial minds and to all persons of experience.

The reasons why the medical man should notify appear to be so plain: he alone is qualified to diagnose the disease; he alone—bearing in mind the ignorance, poverty, and other disqualifications of large numbers of persons—is qualified by his education, his appreciation of the necessities of the case, his freedom from interest, prejudice, alarm, or confusion to notify it; and he would by his direct action save much unnecessary delay.

As a fact, where notification is carried out, it is nearly always by the medical man, even under the dual system.

The householder, on the other hand, is disqualified to report with promptitude and certainty by a number of circumstances, partly from reasons already stated, and also for some others, as want of time and opportunity. One insuperable obstacle would be created by the impossibility of supplying every householder with notification forms, and if that difficulty could be surmounted the forms would soon be lost. It is desirable, nevertheless, to hold the householder responsible to meet cases where a medical man is not called in.

In one town only has notification by the householder been tried, viz., Greenock, and, as might be expected, the results are very unsatisfactory, as only something over 50 per cent. of the cases came to the knowledge of the sanitary authority; but even under these circumstances the death-rate of the town diminished progressively and considerably; it is therefore clear that with a more complete system a proportionately greater advantage would have been gained. Dr. Wallace, medical officer of health of Greenock, concludes a very valuable and interesting report by expressing a fear 'that no further material improvement will take place from notification by the householder.' He is forced to the conclusion that the only satisfactory method of notifying infectious disease would be to throw the responsibility on the medical practitioner, as well as on the householder; in other words, the dual method.

It has been urged as an objection against notifica-

tion, and this objection holds good in the case of the householder, as well as of the medical attendant, that it would be injurious to business. This is possible to a certain extent, but my experience shows that it is a great advantage by removing real danger, and so permitting the business to be carried on with safety. In several instances I have had employes in large establishments removed to hospital to the advantage of the patient, and to the great relief and protection of the other inmates and the public; the proprietors have been shrewd enough to discover the advantage, and grateful for the assistance rendered. In such cases, of course, removal is carried out as quietly as possible, measures of disinfection and precaution are judiciously conducted, and no publicity results. But even should there be publicity, and the business suffer in consequence, either through customers avoiding the shop or the latter being temporarily closed, surely this is a smaller evil than the disease being allowed to remain unreported, and left to spread itself broadcast.

Circumstances have come to my personal knowledge which clearly prove the necessity of the sanitary condition of lodging-houses being known. A short time ago two Birmingham artists who had been to Jersey for a few weeks returned home suffering from typhoid, and one of them died; the disease was traced to their lodgings. Such cases are quite common; people leave home to recuperate their exhausted energies at a maritime or other health resort, and in some lodging-house or hotel contract a dangerous, often fatal illness. Notification would prevent such horrible catastrophes, and I am fully convinced that the hotels and lodging-house keepers would be benefited, instead of prejudiced, by the arrangement. If they were alive to their real interests, they would court examination and certification of the sanitary condition of their establishments rather than attempt concealment of defects and dangers; indeed, some hotel-keepers do actually have their hotels systematically examined and certified by a competent person, and such a course cannot fail to inspire confidence in their guests.

Milk shops and schools are particularly liable to prove centres of preventable sickness and death, unless cases of illness in them are at once notified. It is wonderful to find any one prepared to contend that the proprietors of trade and other establishments should be protected at the expense of the whole community, and it implies a singular excess of innocent belief in the perfection of human nature to expect them in all cases to give notice of the danger in their midst, when at the same time they believe that their interests will be thereby prejudiced.

The absence of adequate and suitable hospital accommodation has been cited as an argument against notification. The objection has, however, much less force than at first sight it appears to have. Very much can be done without a hospital, though I am far from supposing that hospitals are not necessary and indispensable. There is, however, very generally a backwardness on the part of the sanitary authorities to provide them on account of the expense, and some powerful influence is required to put them in motion. It is a fact, proved by experience, that nothing conduces so much to this result as notification. The daily receipt from medical men of reports of zymotic cases that require isolation, which is not being obtained at home, inevitably leads to the provision of hospital accommodation, which otherwise would have been neglected, so that the

absence of hospitals actually becomes an argument for, instead of against, notification.

On the other hand, the existence of hospitals and of sanitary organisation, costly as they are, are comparatively useless without notification; and, indeed, without it the provisions of the Public Health Act, particularly those included in sections 120-143, are a dead letter.

The absence of notification, full and complete, has a relation to the extent and cost of hospital accommodation, which is worthy of notice. For instance, supposing every case of disease be reported as soon as made out, the first cases would receive proper attention and isolation, the disease would be nipped in the bud, and a very small hospital would suffice; but if, on the other hand, first cases are not reported, the stamping-out process fails, the disease rapidly extends and becomes epidemic, and then the most gigantic hospital fails to meet its demands. This relation between notification and cost of hospital accommodation, without regard to other considerations, seems to me a matter of the greatest importance; and the fact should not be lost sight of that the main value of a hospital for infectious diseases is to treat first cases and prevent epidemics, and not to treat thousands of cases which might, with proper care, have been prevented.

In conclusion, I would point out how little can be said against notification, that what is urged against it is, for the most part, of a hypothetical and speculative character, and that its principal opponents are persons who have had no actual experience of its working. On the other hand, both the public and the medical profession in those thirty-eight towns where it has already been submitted to a practical test, accept it with satisfaction. Would they do this if it proved on trial as objectionable as it was predicted? Why in these very towns medical practitioners, who were at first bitterly opposed to the plan, have, on seeing the results of its operation, ceased their opposition, and have become its most loyal and valuable supporters.

I trust the medical profession is being gradually educated up to a proper appreciation of its value, and to a becoming sense of their duties with regard to it. It would be a subject of the profoundest regret to find them in prolonged antagonism to a measure which is necessary to the public good, as has already been abundantly proved.

Such opposition can only be based on mistaken views with regard to the influence of notification on public health, on strictly professional interests, or on sentiment. It is clear that the first is benefited by it, it would be difficult to show that the second would be in any way prejudiced, and the third ground requires no serious consideration. The medical profession is, I am sure, too noble and too generous in its aims to let mere sentimental objections or considerations of self-interest, or a false professional *amour propre* stand in the way of the public weal. We are the servants and not the masters of the public, and it has been usual to regard our profession as the most philanthropic, benevolent, and self-sacrificing of all; but I fear that a continuance in opposition to a great sanitary step forward is calculated to jeopardise its reputation, and not the less so because while a section of the profession is hanging back, the practical common-sense and prudence of the nation at large, as shown by the action of a considerable number of towns already, will step in and do the work without its assistance.

RIGHT OF THE STATE TO EN- NOTIFICATION, AND THE METHOD OF DOING IT.*

ALFRED CARPENTER, M.D., J.P.,
Chairman of Council of Sanitary Institute.

AS I do in the main the observations of Dr. Hill as to the necessity for early I wish to point out some of the difficulties are in the way of doing it as is by some earnest sanitarians, and at the same time give a short history of the progress been made in that direction. I agree with the proverbial statement that 'a spark is of matter which may kindle a world,' and that the great object of the sanitary world is the presence of that spark before it reproduces its kind, and that the method which will give the most complete and in practice will be more satisfactory which may be perfect in theory but for reasons not so efficient in action. The first method as to method came from Manchester Sanitary Association did twenty years ago which the Society of Medical Officers of Health suggested as the method but failed to do it for want of funds, the day refusing to help them in their method. The Manchester Association published a list of all new cases of diseases coming in at the various medical institutions in Manchester and Salford. The sanitary section of the International Statistical Congress held in the year had considered the subject and had decided the method of doing it. The congress decided as a duty upon governments to get the method in the usual way, and pointed out that as to the position of the onset of the disease of more importance than were the actual mortality, a principle which I had at various local meetings held for sanitary progress before the congress alluded to. The returns gave timely warning of the foci where it might be expected that infectious would spread, as spread they did. Manchester Government assistance, did that on was unable to do. Attempts were soon made in different parts of the kingdom to provide means, but they were only 'flashes in the pan,' not persistent. The late Dr. Lankester brought the matter to the notice of the Social Science Association on June 5, 1871, at their rooms in the Strand, Mr. W. Farr being the chairman at that time. Dr. Lankester urged that the State should be responsible, as regards those children who were vaccinated, and that a Court of Summary should have them vaccinated in spite of the fact that heavy fines should be inflicted on medical men who attended cases of small-pox, and not at once notify to the local authority its presence at that particular place. The first suggestion made in a general meeting of his country, that a penalty should be put on a man for not notifying to the local authority the fact of the fire, although it had been suggested that the local authority ought

to be fined for allowing the fire to extend itself. I had urged this view because the foci of disease could not become persistent if the local authority did its duty, and insisted upon local cleanliness, with the generous distribution of a pure water supply.

The subject of notification of small-pox, upon the motion of the late Dr. Stewart, was referred to the Committee of the Health Department of the Social Science Association to consider and report upon, as to what steps could be taken to effect the desirable object of stamping it out. It was discussed and re-discussed at the Congresses of that association without any satisfactory result. At Brighton, in 1875, it was resolved to recommend the Council to take into consideration the desirability of promoting by legislative enactment that all cases of an infectious character should be reported to the medical officer of health of the district, but to meet objections made in the meeting the reporter was not distinguished.

Dr. Littlejohn is said at that meeting to have strongly opposed the resolution as it stood when first considered, viz. 'that it should compel medical men to report.' He said veterinary surgeons were not called upon to send certificates under the Contagious Diseases (Animals) Act to the county authority, and he considered that it would be 'invidious and monstrous to throw such a responsibility upon medical men, instead of casting it upon the man of the house where the case took place.'

In the same year, 1875, the North Western Association of Medical Officers of Health memorialised the President of the Local Government Board, in favour of putting medical men in a criminal position if they did not report to the local authority any case they might be called upon to attend. The subject was again publicly discussed in London on April 29, 1876, when, at the request of the Health Committee of the Social Science Association, I read a Paper upon the right of the State to obtain early information of the appearance of epidemic or infectious disease in a given district. I discussed whether the medical attendant ought to be the informant or not. In that Paper I dealt with the subject from its various aspects, *pro* and *con*. A very careful consideration led me to conclude that there were even more than two sides to the question under consideration, and that it was not so absolutely one-sided as the Social Science Association and Northern Medical Officers of Health Society at their various meetings seemed to think. The Chairman (Dr. W. B. Richardson), in summing up, said that in the discussion four distinct views had been enunciated.

1. That the duty should be absolute upon the medical attendant under a penalty for neglect.

2. It should be upon the legal representatives as head of the family, or of the household in which the case occurred.

3. That there should be a dual notification, that is notification by both parties. Whilst the 4th made it the duty of the medical attendant to inform the head of the household in writing as to the infectious character of the disease, which information the householder should be bound, under a penalty, to transmit to the local authority.

Each project had been supported in the discussion by about an equal number of speakers. The last view was the system advocated in my Paper, and is the plan which, to my mind, was most likely to effect the object we all had in view.

The divided councils at Adam Street did not get

* at the Conference organised at the International Sanitary Congress, by the Society of Medical Officers of Health, the Sanitary Institute of Great Britain, and the Public Museum of Health, London, 1884.

the matter settled. It was again taken up by the Society of Medical Officers of Health, and at a meeting held December 15, in the same year, certain resolutions were proposed; and after several suggestions and amendments had been made, it was unanimously resolved that—

1. Infectious disease ought to be reported by the householder to the sanitary authority without delay.

2. Every medical man attending a case of infectious disease should give immediate information respecting its nature to the occupier or other person responsible for reporting to the sanitary authority.

It does not appear from the report of the discussion at that meeting, which was presided over by Dr. Buchanan, that any proposal was made that medical men should be subject to a criminal prosecution if they did not disclose the nature of the disease to the householder, much less suggest that they should be criminally prosecuted if they did not do so to the local authority. The Chairman, in summing up the discussion, said he thought it the duty of the society to affirm the principle, without, however, making it compulsory under penalty upon the medical profession to give the sought-for information. He (Dr. Buchanan) felt persuaded that as soon as the profession found itself morally bound to do a thing, there would be no ground for suspecting any evasion of the duty even although there was no legal compulsion.

The Parliamentary Session of 1876 witnessed the introduction of clauses in Local Acts giving the power to the local authority of prosecuting medical men who did not notify the existence of such disease to the local authority. Huddersfield introduced such a clause, which inflicted a penalty not exceeding 10*l.*, but which was partial in its application. The subject was handled in a masterly manner at the annual meeting of the Social Science Association at Liverpool in 1876 by Dr. Francis Bond, who argued in favour of the householder being the informant under a penalty, and that medical men should make the communication to him as a moral duty.

In the following year the Town Council of Coventry passed resolutions having the same effect as indicated in the course which Dr. Bond had suggested at Liverpool, and Dr. Ransome urged the same course as essentially necessary in a paper which he read to the National Health Society in May 1877.

About the same time the North-Western Association of the Medical Officers of Health again approached the President of the Local Government Board, but this time they suggested that the householder should be the informant, and that the medical attendant should be liable to a penalty if he did not disclose the nature of the case to the householder or person responsible for the care of the patient. Memorials were also sent to Mr. Sclater Booth by various sanitary authorities calling upon him to introduce a measure into Parliament for the purpose of effecting legislation in the direction thus indicated.

A further step was also taken by the town of Bolton, which obtained a clause in an Act of Parliament putting a penalty for non-disclosure upon both householder and doctor, the doctor being liable to a penalty not exceeding 10*l.*, but entitled to a fee of 2*s.* 6*d.* for notifying.

A temperate and well-written paper on the subject was read at York in July 1878, by Mr. North, to a

combined meeting of medical officers of health for the Northern, Western, and York Societies, in which the difficulties to be encountered by compulsory notification were placed before the members. It did not convince the various medical officers of health assembled at that meeting. They found themselves so often foiled in their endeavours to arrest disease because foci had been conveyed to many places before information reached them as to its existence that they still insisted upon going to the fountain-head for the information, in all those cases at least which came to the cognisance of the members of the medical profession. The advantage and saving of trouble by this course to medical officers cannot be doubted, and if all cases of infectious disease were attended by medical men as a matter-of-course, it would, if carried out efficiently, do what the medical officers require; viz, give them intelligence as to the whereabouts of dangerous infection. But no one can read the reports of the medical officers of health from all parts of the kingdom without coming to the conclusion that the greatest spread of infection is brought about by those cases which are not under orthodox medical care at all, and that notification by the medical profession alone would not effect the object, but rather lead to ignorant attempts to smother up the evidence, and in the end to raise more persistent, and more widespread outbursts. There was a necessity in the minds of medical officers of health for dual notification; and all the Local Bills introduced into the House of Commons in this and succeeding years, contained clauses requiring the medical attendant either with or without the householder to notify to the local authority under penalties.

In 1879 the Local Government Board also made a step in advance by an order dated February 12, which imposed the duty upon all medical officers employed by them of notifying any case of dangerous, contagious, infectious or epidemic disease to the sanitary authority of the district immediately upon its occurrence; it also enabled medical officers of health to obtain such information as to sickness and death among pauper patients, as might be thought necessary for their guidance; and later in the year the order was made to extend to the medical officers of district schools.

I now refer to the action of the British Medical Association, and to give credit to those to whom it is due. The first note was sounded by that body soon after Dr. Ransome had moved in the matter at Manchester, for he introduced the subject to the notice of the Association at Leamington in 1865, and procured the appointment of a committee to consider the registration of disease. Various reports were made by that committee, and in 1875 it was distinctly stated that the authoritative declaration of the nature of the disease must necessarily come in the first instance from the medical attendant; but the committee also expressed their opinion that the proper individual to make return should, in the first instance, be the householder, or the person in charge of the case. I had dealt with the matter in this direction in the address upon public medicine which I had the honour to read at Sheffield in that year. The subject was then referred to the Parliamentary Bills Committee, and voluminous reports have been presented from time to time, and accepted by the Association, and the moral duty of communi-

ating that information to the householder has been then insisted upon. The report of the chairman of the committee (Mr. E. Hart) upon the subject is a masterly *résumé* of the action of the committee, and would be studied by all who take interest in the matter. A discussion took place at Ryde in 1881, when Mr. Michael, Q.C., proposed an amendment to the report, which amendment cast the duty on the medical attendant, and made its neglect a penal act, which was lost by a large majority.

At Worcester, in 1882, the subject was brought prominently forward both in the Public Health section, of which I was president, and in the general meeting. The result of the discussion which ensued was the overwhelming defeat of Mr. Hastings's resolution which made neglect to report, a penal act, and the following proposal was adopted—'That whilst desiring compulsory notification of infectious diseases, the Association wishes to express its opinion that the compulsion to notify should be placed upon the householder as his duty as a citizen, and not upon the doctor.' The subject continued to be debated in various quarters, and on April 26, 1881, a deputation waited upon the President of the Local Government Board, which was formed by representatives of the British Medical Association, Sanitary Institute of Great Britain, Society of Medical Officers of Health, Social Science Association, National Health Society, and of the Vestries and District Boards of London, to ask the Government to legislate upon this and other subjects connected with measures necessary to guard the public health from the danger of infectious diseases.

One of the sequences of that deputation was the appointment of the Hospitals Commission to inquire respecting small-pox and fever hospitals, the extent and sufficiency of hospital accommodation, and, with other matters, 'to insure as far as practicable the protection of the public against contagion.' Having had the honour of being appointed one of the members of that Commission, I directed my attention especially to this part of the subject, and carefully examined the witnesses who were able to speak with authority upon the matter. The report which we presented to the Queen, states very distinctly 'that notification should in all cases be obligatory upon one or more of the following persons—the patient, those in charge of him, the occupier of the house in which he lodges, his medical attendant or any relieving officer (if a pauper) to whom he may apply for assistance.' In effect, the report says it is only by the medical attendant (if any) that the disease can be intelligently notified, since it is only he who can be presumed to know what it is, and who has no interest in concealing it; but it is represented that to impose that duty upon him directly and undeservedly would interfere with the relation which ought to exist between him and his patient, and might prevent the aid of a medical attendant being sought at all. If this be so, it may be sufficient that the medical attendant should be required by law to furnish to persons in charge of a patient, or the owner or occupier of the house in which he lodges, certificate of the nature of the disease, stating whether proper isolation can or cannot be secured without removal, and when removal is necessary, stating also to what extent the case is urgent or severe. 'The persons to whom this certificate is given should be in like manner required by law to forward it at once to the medical officer of health.

The medical attendant should, we think, in justice be entitled to claim a fee either from the patient or from the sanitary authority for every such certificate of his which reaches the medical officer of health, and which he may forward himself if the patient so desires.

Evidence upon these points was obtained from various societies—such as the Medical Officers of Health, the Sanitary Institute of Great Britain—as well as the numerous witnesses who had personal knowledge of the behaviour of small-pox and other infectious diseases.

I now come to the last phases of this important matter. Mr. Hastings introduced a Bill into the House of Commons for the purpose of putting a private medical man into the position of a criminal if he did not become a State official, whenever he came into contact with infectious disease, whether he was willing to be a State official or not. The Bill came on for second reading on June 27 in last year. The House was counted out immediately after Mr. Hastings's speech in its favour, and the Bill was not proceeded with. The Government had been previously interviewed by Mr. Hastings's followers, but they would not pledge themselves to support a general Act, although pressed to do so by some men who are notably anxious to make the medical profession occupy a secondary position in the country. In October of last year the Social Science Congress held its meeting at Huddersfield. It might have been supposed that after the defeat of the President of their Council on this matter, that as Huddersfield was the first town which obtained the advantages or disadvantages which attach to a penal clause, and is the town in which compulsory notification has been the longest in operation, we should have had a convincing discussion as to the benefits or injury which had resulted to the town from the passing of the Act. It does not appear that a single word was said upon the subject by either side. Mr. Hastings did not raise the point, and no other person said a word about it; and although the Social Science Association had been on former occasions so very positive about its benefits, and were actually meeting soon after their President's defeat in the very town most capable of producing convincing proofs, if they were forthcoming, as to the advantages of the Act; there was a silence on the subject which to me is inexplicable, unless on the view that the results do not correspond with the prognostications, and that it would not have been safe to excite a discussion among those capable of proving the negative.

If towns having the compulsory clauses in operation are not able to show better things than can be shown in those places in which only a moral obligation to disclose exists, I think it must be evident to those who wish to prevent us trusting too much to a paternal Government that we had better steer clear of too much compulsion, and trust a little more to moral obligations. There is a strong feeling in the commercial world against professional men, such as lawyers, commission agents, auctioneers or engineers, accepting a commission from both sides in a given case, and being engaged as advisers for both sides in any commercial transaction; and I fail to see any difference in the case of a man who is employed by a private and responsible individual to cure him of his disease being compelled to accept a fee for disclosing something which may be used by the local authority to the injury of his client and employer.

The object of notification is not simply a registration, but a repression of disease ; and if the repression is brought about, the means whereby the repression is produced is of no consequence. If the fire is put out, it would be curious indeed if the local authorities complained, or asked for the infliction of a penalty upon the person at whose house the fire occurred because they had not been informed of the fact, by the man who had put out the fire, whilst it is certain that when rewards were offered for the discovery of fires, much false information was forthcoming at the fire station. There would be reason in the application if the fire had not been put out and several other premises had also been consumed in the conflagration. It might be reasonable to ask for it, but here again there might be a difficulty if it could not be proved as to the nature of the case, and in which house the fire first appeared. I am curious to know how many certificates have been sent in, reporting cases which turned out after all to be false alarms instead of true reports. If you look into the evidence given to the 'Hospitals Commission,' it will be seen that it was not always clear that a given case was small-pox, or typhus, or scarlatina, or even infectious disease at all.

In some cases it might be important that the medical attendant should be put into the witness-box, as against the householder, but if he is made a *particeps criminis*, his mouth is closed as regards the prosecution ; he cannot be called by the local authority, he cannot be made to convict himself ; whilst if he has not informed his employer as to the nature of the disease (as it is possible to be alleged by that householder in his defence), he would be guilty of a moral wrong which if proved against him would be of much more serious consequence to him than any money penalty, which penalty if inflicted would be certain to be paid by his employer as part of the price of his silence, and as payment for the prosecution which had been instituted against him. If an employer is determined to break the law, and his medical attendant will acknowledge to having committed a moral wrong for the purpose of assisting in the fraud, the same attendant will not disclose, if the employer agrees to hold him pecuniarily harmless. The evil will be as great in the one case as in the other. Whilst the medical attendant cannot be called for the prosecution, he will be able to appear as a witness for the other side, and if he likes to say so can aver that the prosecution is mistaken as to the identity of the case. To my mind it is far better that the local authority should have the moral support of the medical profession than run the risk of having a '*non omnia possumus*' set up by the passive action of a large section of the medical profession in a given town. Whilst the fear that the medical attendant is bound to directly disclose, could not be used as an argument against the employment of an orthodox medical man. If such a man be employed to treat infectious disease, and if the householder does not disclose it, it will be ten times over more to his interest to prevent the spread of the disease which he is hiding up, and in his own interests as well as for his medical attendant's sake, to use the most persistent endeavour to extinguish the disease and prevent any knowledge of it reaching the ears of the local authority in consequence of that extension.

A disagreeable medical officer of health, or the fussy and interfering action of an acknowledged rival, the impropriety and the public scandal of one

medical man taking legal proceedings against another, and that other possibly his superior in social position and in professional standing, ought not to be countenanced by medical men at any rate. However satisfactory it might be to some others that such proceedings should be taken, there will always be in every profession some men who will see in the opportunity of throwing dirt at a professional superior that some of it will stick, and all men are not able to see the motive for the malicious action.

Until all medical officers of health consist of either consulting practitioners or men who are not in practice at all, there certainly will be some who will be able to hide for a time the malicious character of their action, and try to injure another man's reputation for the purpose of establishing their own, not seeing that if their own is not capable of being established without the other man is damaged, they are proving their own littleness, and their own incapacity to excel their neighbour in the estimation of the people simply by professional work. I am very much opposed to placing any such power in the hands of professional rivals. The method by which action may be taken is so likely to be moved by motives out of sight ; men will so often try to pose as energetic and self-denying officers, and are but too often able to inflict undeserved damage upon a rival practitioner before the real motive is seen, that I for one set my face against the new departure which is being made in this direction ; and I aver that we do not want too much of compulsion in our sanitary work. It does not follow that a despotic government will always be benevolent. It is found by experience that as good results have been obtained in districts in which notification is voluntary, as in those places in which it is compulsory ; indeed the incidence of infective disease is higher in Huddersfield, in Bolton, in Edinburgh, and in Dundee, than it is in a number of places in which there is no compulsion upon medical men, showing at once that compulsion has not extinguished the diseases which are proposed to be stamped out by it. If those towns could show that the disease had been completely arrested by the power they possess, there would be grounds for argument in favour of the extension of compulsory notification to other places, but whilst the cases continue to be nearly, if not quite as numerous, whilst the mortality continues to be considerable, it is evident that there is much more to be done by the local authority in removal of the causes which promote the spread of infection, than simply by enforcing professional notification ; and whilst ready to concede that the householder ought to notify as a part of his duty as a citizen of a civilised country, I think it would be much more likely to bring the whole force of the profession to bear upon the subject if it was insisted upon as a moral duty to the State, that a written notice should be given by the medical man to the householder as a part of his prescription. I would rather that the neglect to perform a moral duty should be dealt with by the medical licensing authorities or by the Medical Council than it should be made a penal matter to be dealt with in a court of summary jurisdiction by those who will not always be able to see the motive for the prosecution or the medical bearing of the case, and the possible differences of opinion which will sometimes arise, and which will be best dealt with by men of high standing in the medical profession. Let us try to get a general Act which shall apply the same law as to infectious

disease as does now apply to contagious diseases among animals. Let us see the result of the general application of such a law, and if after a time it is found to fail in its effect there will then be a sufficient reason for placing penalties upon a whole profession for not performing that which can only be regarded in the light of a moral duty. To place a power of prosecution, even under such circumstances, in the hands of a fellow-practitioner would be wrong, and I should urge that in such a case a prosecution should only be instituted with the consent and by the action of the Medical Council of Great Britain, so as to get rid of the possibility of professional rivalry, and vindictive or malicious action on the part of a professional brother. I am bound to say that the medical officers of health have not used the power they possess against their professional brethren in the twenty towns which have now a compulsory clause, and it is much to their credit that penal proceedings have not been taken by them, but they have also to show that if it were penal on the householder only, as a citizen of the commonwealth, it would not have been so effectual as they say it has been. I think it would have been equally so, and that the same results would have been obtained in the one case as it is assumed to have been obtained with the dual notification. The fear which does arise among the people, that medical men will be informers against the patient's interest could not have any foundation, and we should not find so many cases reported which have not been recognised by an orthodox practitioner, because they have not been placed under any medical man's care.

THE SANITARY AND INSANITARY HOUSES AT THE HEALTH EXHIBITION.

By HENRY M. MAVOR.

THE preparation of these houses has been considerably delayed owing to a variety of causes beyond control; but now, fortunately, they are fairly complete, or at least sufficiently advanced to invite a careful inspection, not only from those who have a thorough knowledge of the subject, but also those to whom sanitary matters are more or less of a mystery. It is perhaps as well that the delay has taken place, as the opening of this exhibit should give an impetus to, or further interest in, a study which is fast becoming general; and the sanitary appliances and different kinds of apparatus scattered throughout the other parts of the Exhibition prepare the untechnical mind for the continuity of principle here shown. It will be understood that these houses have been specially erected to place before the public in the simplest manner a contrast between good and bad sanitary arrangements of an ordinary dwelling-house, and the actual working in every-day use. There has been no attempt to exaggerate the defects of the old system, but merely to bring before the public specimens of common errors to be found in the majority of homes, and from which errors many of the best built and most sumptuously fitted houses are not exempt. To render the comparison more easy, the various arrangements are disclosed to view in such a way that the important points are clearly seen, and legibly printed and numbered labels arrest the attention. As a contrast, the sanitary

tion and principle, in addition to which other points bearing upon health are illustrated, such as electric lighting, ventilation, floor construction, and other matters.

Entering by the basement of the insanitary house a large dust-bin is noticed, being a portion of the area framed in. This, of course, means that it is a fixture, and as such it cannot be readily emptied, much less cleaned. The arrangement as it should be is shown in the area of the sanitary house as a galvanised iron bin, which holds only a small quantity of refuse, thus necessitating its frequent emptying, and, being movable, this is easily done. The condemned 'bell-trap,' communicating directly with the drain in the area, and a similar form of construction to the scullery sink, are here to be seen, and, of course, forbidden. The damp walls point to the want of a 'damp course,' and the uselessness of an improper material, such as tarred felt, which soon decays, is adverted to. The floor joists are here resting on the ground, and, as everybody knows, there can be but one result to this. At the same time the drains are disclosed to view, the stoneware pipes being jointed in clay, and the objections to this material will be pointed out, such as the impossibility of making a water-tight joint, and the liability of being washed out or squeezed out. A very usual error of laying some of the branches at right angles thus causing stoppages, to say nothing of bad jointing, is then noted. The point next emphasised is No. 10, which shows an arrangement which we fear is only too prevalent, that is, a cistern for drinking purposes, supplying also a servants' water-closet, and a tap over the scullery sink. The overflow pipe discharges into the drain, it is placed in an inaccessible position, and it runs the risk of receiving the leakage or overflow from a water-closet immediately over. When these many evils are shown in conjunction, and are known to exist, it will surely induce owners and tenants to put their houses in order. The faulty construction of an inside soil-pipe is given, the joints being only partially filled with putty, the foot of this soil-pipe being connected with the drain by a right-angled junction, and not as it should be by an easy bend: an accumulation would naturally occur here with direful results. The drain is continued and cut off to form a 'dead end,' which would allow of a permanent lodgment of filth, or, what would be worse if it became unstopped, the basement would become gradually overrun. It is nothing uncommon to find, even in large houses, a water-closet in the middle of the building, without light or ventilation, and an instance is given here combining faulty apparatus and insufficient flushing arrangement. The following ordinary form of drain is illustrated:—Stoneware pipes 6 inches in diameter, badly jointed in cement at the top, but open at the bottom, laid, as is constantly done, to an insufficient fall, and with no trap between the house and the sewer. A gas stove, without provision for carrying off the vitiated air, points to a trouble not unknown, and reminds one of the charcoal braziers in use on the Continent, the fumes from which occasionally lead even to loss of life. Ascending to the ground-floor we find another water-closet in a bad position with the pan apparatus and the inevitable D-trap, this being the one, as before described, over the cistern in scullery. As there are still many advocates for the use of the lead D-trap, we would advise them to stroll round the Exhibition and see

some of the specimens of the apparatus which have recently been taken from different quarters, and these clogged and corroded examples may at least cause them to hesitate. Not content with this form by itself, the plumbers of old often connected the other services with it, and the lavatory and bath are here shown in communication, and defy contradiction. A notice on the wall brings to mind the former use of arsenic in the colouring matter used in wall-papers, for although it was known that this substance was required, or supposed to be required, to produce a good green, it was presumed that other colours were exempt from it, but it was and is news to many minds that it was used nearly all round. In the insanitary house these arsenical papers are used throughout, the reverse being the case in the other example. The rain-water pipe being connected with the soil-pipe shows again a mistake of which the danger is often underrated, mostly arising from a false sense of economy, and occasionally the argument is adduced that it helps to flush the drain, forgetting that the drain may in a sense flush the pipe—with sewer gas. Any hole or corner is supposed to be good enough for a housemaid's sink, and we are shown one badly placed—no light or ventilation, and connected with a water-closet. The bedroom water jugs and bottles would be filled from a tap deriving a supply from a cistern also in connection with a water-closet—nothing unusual in this. Matters are not mended when we see the bath service introduced into the generally faulty system, and the 'last straw' is arrived at on finding the cistern in the roof impossible to get at, and communicating 'all round,' supplying anything or everything, if, by doing so, a few feet of piping may be saved.

So much for things as they are. In the sanitary house we find them mostly reversed, but with the addition of many points which the old principles were not able to contain. We are first asked to look at a simple method of ventilation which consists of making the bead on the window-sill two or three inches deeper than usual; then by slightly raising the lower sash air is admitted at the meeting-rails only, and passes into the room in an upward direction, avoiding draught. A funnel and tube over the gas brackets form an efficient means of carrying off the products of combustion, taking the vitiated air through the wall to the exterior. A point of great importance, yet easily managed, is to place the cisterns in a space adapted for the purpose, where they can be easily examined, as exemplified here. A separate cistern is used for drinking purposes, with an overflow passing through the outside wall discharging into the open, so there is no connection with any drain in any way. On the supply-pipes are fixed stopcocks, so that the water may be shut off at any part to enable repairs, &c., to be made without interfering with the remainder. The usual winter trouble of a 'burst pipe' can be avoided by adopting a draining-tap (No. 77), by which the 'main' can be emptied, and much annoyance saved to the householder. The water-closets in this house are well lighted and ventilated, the valve apparatus, such as shown by many makers, being used in one case, and also an improved 'hopper,' with a flushing rim all round the basin. It is needless to recapitulate the many improved forms here in use; suffice it to say that types are to be found by the score throughout the Exhibition, but they have a double value and meaning when

placed *in situ*; but there is one point which is not always to be seen, viz., the 'inspection chamber' (No. 100), which allows of an easy mode of access for inspecting and cleansing the drains, which are continued through the floor of the chamber, with open-glazed stoneware channels, the drains entering these channels being four in number—viz., surface water, waste water, soil-pipe, and w.c. in basement. The soil-pipe, of course, is carried up the full six above the roof as a ventilating pipe, and a through draught is obtained from the manhole in the front area.

DEEP DRAINAGE AND SEWAGE PURIFICATION IN THE BLACK COUNTRY.

(FROM OUR OWN CORRESPONDENT.)

[First Article.]

THE question of deep drainage and sewage purification has now for some years been occupying the more or less serious attention of the various local authorities in the large and populous section of the Midlands, known as the Black Country. Scientific opinion has long recognised the fact that the supply of pure water, efficient drainage, and improved knowledge and habits of sanitation effect a salutary reform in the moral and social life of the inhabitants of populous centres, and public opinion has within the last few years come to recognise the importance of such conditions and to urge their fulfilment. Birmingham was about the first in this part of the country to take active measures in this direction. But though they have done a great deal, especially in regard to the interception and purification of sewage matter, they have yet a great deal to do before the town can be considered in a thoroughly satisfactory condition. Wolverhampton and Walsall have likewise accomplished much in the same direction, and at the present time most of the urban sanitary districts within the catchment basin of the Upper Tame are either engaged in carrying out schemes of sewerage, or in the preparation of such schemes. Deep drainage is even now a thing almost unknown in the practical experience of the district, and the difficulties in the way of its accomplishment are so many and so great, that one is not much surprised to find the question shirked as much and as long as possible.

The passing of the Rivers Pollution Prevention Act in 1876 largely assisted in bringing matters to a crisis. By sect. 30 of the Birmingham Waterworks Act of 1866, provision was made as to the use of the Tame as a source of water supply by the Birmingham Waterworks Co., also limiting the quantity of water to be taken therefrom, with, however, power of free use of the water in case of emergency, such as long continued frost, drought, or other unavoidable accident, or in the event of the water being certified by the Board of Trade to have become pure and fit for domestic purposes. When the Birmingham Corporation took over the water supply of the town the powers given in the Act were transferred to them, by virtue of the Corporation Water Act of 1875. It is thus easy to see how important a matter it is to Birmingham that the River Tame should be kept free from sewage contamination, and the great assistance the enforcement of the Rivers Pollution Prevention Act would be to them in this direction.

How difficult an object the purification of the River Tame is to accomplish under present conditions may be gathered from the fact that a great part of the sewage of some twenty parishes, with more than 20,000 population, passes into it. From Walsall alone, for instance, above a million and a half gallons of unpurified sewage were emptied daily into the Tame previous to carrying out of sewerage works here. The volume of the river at the point of entry of this quantity of filth is comparatively small, quite inadequate to render it innocuous, and before it became inoffensive it would be carried through the parishes of Great Barr, Perry Barr, Hamstead, West Bromwich, Handsworth, Aston, and the district under the control of the Birmingham United Drainage Board. As we have said, the passing of the Rivers Pollution Prevention Act brought matters to a crisis. That Act provides that every person (including Corporate bodies) who knowingly permits to flow into any stream any solid or liquid sewage matter, shall be deemed to have committed an offence, rendering him or them liable to a penalty of 50s. per day. It will readily be seen that such a stringent provision came as a boon and a blessing to the authorities charged with the water supply required for the 400,000 inhabitants of the Midland metropolis, and they lost very little time in giving the offending authorities along the banks of the Tame notice that they must cease to pollute the stream or its tributaries with sewage, or they, as proprietors of the water rights, would have recourse to legal measures for the enforcement thereof. This notice was sent out after the twelve months' grace allowed for carrying out the requirements of the Act had expired, to the whole of the districts the natural drainage of which washes into the Tame or its tributaries. Some of the local authorities also received other and minor notices of a similar character from persons having, or claiming to have, a right to use the stream for various purposes. But the powerful and wealthy Birmingham Corporation was the body to be dreaded, and the local authorities were speedily on the *qui vive* as to what was to be done. There were two courses open to the delinquents, either to withdraw the sewage from the stream altogether, or else to avail themselves of the 3rd section of the Act, which provides that, 'where any sewage matter falls, flows, or is carried into any stream along a channel used, constructed, or in progress of construction, at the date of the passing of the Act, for the purpose of conveying such sewage matter, the person causing or knowingly permitting the sewage matter so to fall, or flow, or to be carried, shall not be deemed to have committed an offence against the Act if he shows to the satisfaction of the Court having cognisance of the case that he is using the best practicable and available means to render harmless the sewage matter so falling, or flowing, or being carried into the stream.' Fortunately for the authorities, in addition to the twelve months' grace allowed from the passing of the Act to enable public bodies who were permitting sewage to pollute a stream to adopt the necessary measures for complying with its requirements, an extension of the period of freedom from prosecution could be gained on appeal to the Local Government Board, if sufficient cause was shown or disposition manifest on the part of the applicants to carry the law into effect at the earliest possible period. The Walsall Corporation was one of the first bodies in this dis-

trict to recognise the gravity of the position, and to take active measures to comply with the terms of the notice served upon it by the Birmingham Corporation. But most of the authorities were very lax. They dreaded to face the difficulties to be encountered in carrying out an efficient scheme of sewerage. They also dreaded the large expenditure that would be required, and the effect it would have upon the rates—and ratepayers. Notice after notice has been sent out from Birmingham, with dire threats of penal consequences, and it was only upon the actual commencement of legal proceedings, or the fixing of a date when such proceedings would be instituted, that some of the Local Boards really and earnestly bestirred themselves in the matter. In some parts of the district an attempt was made to compromise the difficulty by passing the sewage through filter-beds or over sewage farms in a crude fashion. But the Birmingham Corporation, as the parties most aggrieved, declined to accept this temporising with the matter as a final or satisfactory settlement, and pressed for some real and effectual remedy. In the end the authorities have found themselves compelled to go in for more or less elaborate and costly schemes, and also to apply for the protection of an order from the Local Government Board to relieve them from the fear of prosecution while endeavouring to carry those schemes into effect.

Another important factor in the consideration of sewerage schemes in the mining part of the district is the important body known as the South Staffordshire Mines' Drainage Commissioners. The wave of prosperity in the iron trade of the district, which set in during the years 1872-3, caused the mining resources of the district to be subjected to somewhat careful examination, with the result of proving that there was still within it a vast quantity of ungotten minerals which might be reached and utilised if water in the mines could be successfully dealt with and got rid of. An Act of Parliament was obtained in 1873, which has been supplemented by others passed in 1878 and 1882, by which power was given to form a Commission under the above-mentioned title, and to levy rates on the minerals raised for enabling them to carry out a comprehensive plan for dealing, first with the drainage on the surface, and then with the draining of water-logged mines. This was a gigantic task, beset with many and almost insurmountable difficulties. The district is not to any appreciable extent watered by springs from the surrounding hills; but in addition to the rain water there was the constantly-recurring difficulty to be dealt with of the water from the numerous canals which intersect the district, finding its way into the mines through defective works and leakages. This water, a very serious quantity, finds its way into the workings, and has all to be pumped up to the surface—in addition to the accumulation from this and other sources—and conveyed away in the watercourses, which it was the first duty of the commissioners to provide. The position of this Board may really be said to be that of an authority provided by Act of Parliament to take over, maintain, repair, widen, and deepen all existing watercourses within the area of their operations, with power to make others where required, and to compel all parties raising or disposing of water by any means to take due care that it was conveyed into one of those courses, which would carry it to the confines of their area. While they are not an

authority to put in force the Rivers Pollution Prevention Act, they regard themselves as conservators of streams, with power to enforce riparian rights, and also to call upon mine-owners to maintain the watercourses at their proper levels, and to take due precaution against the water escaping therefrom into the mines. For nearly ten years the Mines Drainage Commission has been at work, with the result that after an expenditure of some 300,000*l.*, although the water is gradually sinking, the drainage of the mines is still very far from complete. As the chairman of the Board said but a short time since: 'It was only within the last few months that they had been able to say that the general drainage or surface works were in a sufficiently finished condition to enable them to trace accurately and definitely where pollution was turned in upon the works, or to point out the exact injury which the road *detritus* was doing in the way of filling up the commissioners' watercourses.' These watercourses have cost the commissioners a quarter of a million sterling, and as they are the only means by which the storm water can be kept out of the mines, and by which the water pumped therefrom can be conveyed away, their pollution becomes a grave and serious question which is affected in no small degree by the action of the several local authorities in the carrying out of their respective sewerage schemes. The commissioners can scarcely be blamed therefore for looking to the interests of their own undertaking, and seeking to prevent any interference with or encroachment upon what has cost them so much time, labour, and money to achieve. With this end in view, as also, no doubt, with an idea of furthering them in their work, the commissioners have recently formulated a scheme for combined drainage operations, by which the local authorities would unite with the commissioners in perfecting the surface drainage of the district, and carrying out in conjunction therewith one general sewerage scheme. It was claimed for such a project that the saving to the district, compared with the carrying out of a separate scheme by each local authority, would amount to something like a quarter of a million sterling. On the other hand, something very much in the nature of threats were shadowed forth as to possible action on the part of the commissioners to prevent the *detritus* carried by storm water from entering the streams and watercourses under their control. Several meetings and conferences on the subject have been held, but without eliciting from the commissioners any definite plan upon which a scheme of such magnitude could be effected. There is no doubt if a workable scheme could be prepared, and all the local authorities could be induced to sink their several individualities and consent thereto, a considerable saving would be effected, especially if the commissioners insist upon and have the power to enforce the clearing of storm water from *detritus* before it enters the streams and watercourses, as this would, perforce, involve the inclusion of storm water in every local sewerage scheme, and thus in many cases largely swell the cost. But no such scheme has yet been defined, nor is it feasible that the various interests involved would ever be got to harmonise sufficiently to allow a work of such magnitude to be carried to a successful issue. The local authorities are inclined to doubt the power of the commissioners to compel them to deal with the storm water; and at a conference of representatives of the local boards and town councils of the district,

convened about a month since for the consideration of the question, a resolution was unanimously arrived at that 'in the absence of figures showing how the estimated saving of 250,000*l.* is arrived at, and of the draft of the Bill setting forth the position, liabilities, and benefits to the local authorities under the commissioners' scheme, the meeting was not prepared to recommend the various local authorities to take any further action in the matter.' And at this stage this phase of the question of the sewerage of the Black Country remains at the present time.

In order to the understanding of the difficulties attendant upon the carrying out of deep drainage and the disposal of sewage in this district, it is also necessary to consider the physical formation of the country. The district popularly known as the Black Country occupies the south-eastern end of the county of Staffordshire, and takes in a small portion of the northern end of the county of Worcestershire. The greater part of it drains naturally by the River Tame into the Trent, and thus into the Humber and the German Ocean. The places affected are Aldridge, a portion of Aston, Bilston, Bloxwich, Brownhills, Coseley, Darlaston, a portion of Dudley, Great Barr, a portion of Handsworth, Oldbury, Pelsall, a portion of Rowley Regis and Sedgley, Tipton, Rushall, Walsall, Wednesbury, a portion of Wednesfield, West Bromwich, Willenhall, and a portion of Wolverhampton. Some of these places belong to the mining district and some to the rural district. The area of the mining district is about 52½ square miles, and of the rural district 40 square miles. The district is composed of three main divisions of rocks—the new red sandstone, the permian, and the carboniferous. The bulk of the district lies for the most part upon the carboniferous group of rocks, and a great part is included in the coal measures of these rocks. The annual rainfall of the district varies from twenty-five to thirty inches in that part including Bilston, Coseley, Dudley, Oldbury, Sedgley, Tipton, Wednesfield, and Wolverhampton, to between thirty and forty inches in the other part. The position of so large a portion of the district in relation to the carboniferous rocks has to be borne in mind in practically dealing with the question of sewage disposal, inasmuch as the clay surfaces of the coal measures act so differently to the porous surfaces of the new red sandstone or the permian, being comparatively impervious to percolation, and therefore more advantageously made serviceable for the drainage of surface water. At the same time, the difficulties of dealing with deep drainage and sewage purification are greatly enhanced not only by the honeycombed and rotten nature of much of the ground that would have to be passed through, but also by the expense of acquiring land containing minerals—whether ungotten or in course of working—for the purposes of intercepting and outfall sewers, and for the treatment of the sewage when collected by most of the methods in vogue.

Having now set forth how the question has been brought into prominence, and how it is the local authorities have been compelled to take active measures for effectually dealing with it, as also the many and serious difficulties by which it is beset, we propose in succeeding articles first to say something about what Birmingham itself has done in this direction; and then to point out the nature of the several schemes proposed in various parts of the district, with the probabilities of their successful accomplishment.

REGISTRAR-GENERAL'S LAST QUARTERLY RETURN.

By J. HAMPDEN SHOVELLER.

arterly return of marriages, births, and in England and Wales has just been issued by the Registrar-General. The statistics relating to marriages are for the first quarter of this year, and relating to births and deaths are for the three months ending June last. The marriage-rate showed a considerable decline from that recorded in the corresponding period of the previous year; the birth-rate and the death-rate were below the average. The temperature during the quarter at the Meteorological Observatory, Greenwich, was 52°·5, and exceeded the average for the corresponding period of 113 years. The rainfall amounted to 4·31 inches, which was one inch and a half below the amount.

In the first quarter of 1884 the marriages of persons were registered in England and Wales equal to an annual rate of 12·3 per 1,000 of the population, estimated by the Registrar-General at more than twenty-seven millions of persons.

This marriage-rate was 1·0 per 1,000 above the rate recorded in the first quarter of 1883, and 0·7 below the average rate in the corresponding periods of the ten years 1874-83.

Births of 231,149 children were registered in England and Wales during the second quarter of 1884, equal to an annual rate of 34·2 per 1,000 of the estimated population. This birth-rate was 1·1 above that recorded in the corresponding period of any year since 1869. In the several years the birth-rates ranged from 26·4 in Rutland, 27·5 in Herefordshire, and 29·1 in the metropolitan portion of Surrey, to 39·7 in Lancashire, and 41·7 in Durham. The 231,149 births registered in England and Wales during the second quarter of 1884 exceeded the deaths by 100,000, which represents the *natural* increase of the population.

From the Board of Trade returns it appears that 120,102 emigrants embarked during last quarter from the various ports of the United Kingdom, which emigration officers are stationed at, and excluding foreigners, the emigrants whose origin were 92,451, including 46,345 Scotch, and 38,252 Irish. The proportion of British emigrants to a million of the population of the three divisions of the Kingdom were 1,708 from England, 2,031 from Scotland, and 7,723 from Ireland. Compared with the corresponding quarters, the proportion of emigration last quarter showed a decline in each of the three divisions of the United Kingdom.

The returns published by the Local Government show that the average number of paupers on the last day of each week in the quarter ending June last was 696,931, of whom 173,749 were in indoor and 523,182 outdoor relief. The number of the population in receipt of pauper relief showed a further decline from that recorded in the corresponding periods of the two preceding years.

The deaths registered in England and Wales during the second quarter of this year were 127,946, equal to an annual rate of 18·9 per 1,000 of the estimated population. In the second or spring quarter of 1881 the death-rate was so low as 18·6; with this exception the death-rate last quarter was lower than that recorded in any spring quarter since civil registration was established in 1837. This low rate of mortality last quarter implies that upwards of 16,000 persons survived the three months who would have died had the death-rate corresponded with the average rate in the same quarter of the forty-six preceding years. In the various counties the death-rates ranged from 14·3 in Sussex, 14·7 in Huntingdonshire, and 15·4 in Berkshire, to 20·6 in Staffordshire, 21·8 in Lancashire, and 22·1 in Cornwall. In the principal urban districts comprising the chief towns, and containing an estimated population of nearly sixteen millions of persons, the death-rate last quarter averaged 20·0 per 1,000; in the remaining and chiefly rural population of about ten millions and three quarters of persons, the rate of mortality did not exceed 17·3. These urban and rural rates were respectively 1·3 and 1·7 per 1,000 below the average rates in the ten preceding corresponding quarters.

In twenty-eight of the largest English towns, including London, and having an estimated population of more than eight millions and three quarters of persons, the death-rate during the quarter under notice was 20·8 per 1,000, and exceeded by 0·8 the general urban rate. While the death-rate in London did not exceed 19·9, it averaged 21·6 in the twenty-seven provincial towns, among which it ranged from 16·1 in Brighton, 16·8 in Derby, and 17·2 in Bristol, to 24·9 in Wolverhampton, 25·5 in Manchester, and 25·6 in Oldham. The rates of mortality at different ages in these towns varied considerably; it may be noted that the death-rate among infants in the twenty-eight towns, measured by the proportion of deaths under one year of age to 1,000 births registered, ranged from 82 in Brighton, to 175 in Oldham; that among persons aged between one and sixty years the rate of mortality did not exceed 9·2 in Derby, whereas it was equal to 17·3 in Oldham; and that among persons aged upwards of sixty years, the death-rate ranged from 61·1 in Norwich to 99·2 in Bolton.

The 127,946 deaths in England and Wales last quarter included 28,001 of infants under one year of age, 66,629 of children and adults aged between one and sixty years, and 33,316 of persons aged sixty years and upwards. Infant mortality was equal to 121 per 1,000 births, and was below the average of the ten preceding corresponding quarters. In the twenty-eight great towns the proportion of infant mortality averaged 137 per 1,000 births; it did not exceed 131 in London, but averaged 142 in the twenty-seven provincial towns, among which it ranged from 82 and 92 in Brighton and Birkenhead, to 165 in Preston and 175 in Oldham. Among persons aged sixty years and upwards, the rate of mortality last quarter in England and Wales was below the average.

The deaths registered in England and Wales during the second quarter of this year included 3,603 which resulted from whooping-cough, 3,457 from measles, 2,620 from scarlet fever, 1,674 from diarrhoea, 1,491 from 'fever' (including typhus, enteric fever, simple and ill-defined forms of continued fever), 902 from diphtheria, and 652 from small-pox; in all, 14,399 deaths were referred to these principal zymotic diseases, equal to an annual rate of 2·13 per 1,000, against an average rate of 2·38 in the ten preceding corresponding quarters. In the twenty-eight great towns this zymotic rate

deaths registered in England and Wales during the second quarter of this year were 127,946, equal to an annual rate of 18·9 per 1,000 of the estimated population. In the second or spring quarter of 1881 the death-rate was so low as 18·6;

last quarter averaged 3·13 per 1,000, and ranged from 0·82 and 0·92 in Brighton and in Derby, to 4·30 in Wolverhampton and 4·64 in Liverpool. In fifty other towns this zymotic death-rate averaged 1·95 per 1,000, while in the remaining or rural portion of the country it did not exceed 1·60.

Whooping-cough was the most fatal zymotic disease in England and Wales during the quarter ending June last. The 3,603 fatal cases of this disease were equal to an annual rate of 0·53 per 1,000, which almost corresponded with the average rate in the ten preceding June quarters. The highest rates of mortality from whooping-cough in the twenty-eight towns were 1·29 in London, 1·62 in Bolton, and 1·74 in Liverpool. Among the fifty other towns the death-rate from this disease was equal to 1·54 in Bury and 2·12 in Gateshead. The 3,457 deaths attributed to measles were equal to a rate of 0·51 per 1,000, against an average rate of 0·44 in the ten preceding corresponding quarters; the measles death-rate in the twenty-eight towns averaged 0·94 per 1,000, but the rate was equal to 2·56 in Portsmouth, 3·40 in Oldham, and 3·43 in Wolverhampton. In the fifty other large towns the highest rates of mortality from measles were 1·40 in Bury and 2·75 in Macclesfield. The 2,620 deaths from scarlet fever were equal to an annual rate of 0·39 per 1,000, which was considerably below the average rate in the corresponding quarter of the ten preceding years. In the twenty-eight large towns the highest scarlet fever rates were 1·42 in Cardiff, and 1·67 in Sheffield; among the fifty other towns the rate was equal to 1·73 in Gateshead, 1·79 in Ashton-under-Lyne, and 4·51 in Wigan. The rate of mortality from diarrhoea in England and Wales

was below the average last quarter. The death-rate from fever, which in the ten preceding June quarter had averaged 0·33 per 1,000, did not exceed 0·22 and with the single exception of the second quarter of 1881, when it was also 0·22 per 1,000, was lower than in any quarter on record. The fever death rate in the twenty-eight towns did not average more than 0·23; it was, however, 0·60 in Portsmouth, and 0·62 in Blackburn. The fatality of diphtheria somewhat exceeded the average, though it showed a marked decline from that which prevailed in the first quarter of the year. The highest death-rates from this disease among the twenty-eight towns last quarter were reported in Portsmouth and Cardiff. Of the 652 fatal cases of small-pox registered in England and Wales during last quarter, 34 occurred in Greater London (excluding 87 of London residents in hospitals situated outside Registration London), 50 in Liverpool, 20 in Sheffield, 15 in Wals Bromwich, 15 in Sunderland, 9 in Hull, 9 in Newcastle-upon-Tyne, and 103 in other parts of the country.

The causes of 116,661, or 91·2 per cent., of the total deaths in England and Wales last quarter were certified by registered medical practitioners; and 6,671 or 5·2 per cent., by coroners in inquest cases. The causes of the remaining 4,614, or 3·6 per cent., were not certified; this proportion showed a decline from those in recent quarters. The proportion of un-certified deaths in London was only 1·3 per cent., whereas in the rest of England and Wales it averaged 4·0. In the twenty-seven largest provincial towns the proportion of un-certified deaths averaged 3·4 per cent., and showed the largest excess in Sheffield, Hull, Halifax, and Oldham.

Analysis of the Vital and Mortal Statistics of the Twenty-eight Great Towns, dealt with in the Registrar-General's Weekly Returns, for the Second Quarter of 1884.

ITY STATISTICS OF HEALTHY UNHEALTHY DISTRICTS OF IN.

By ERNEST HART.

ing tables have been worked out from the Registrar-General's reports. They form a statement which was made by me at a meeting of the Sanitary Commission at the Mansion House on Dec. 11, 1883, on the dwelling-house, in moving the resolution for the establishment of the Mansion House Committee, which is for the purpose of forming Sanitary Aid Societies in the various districts of London for the enforcement of existing legislation, and for the promulgation of the law. Up to the present time no statistics have, so far as I have been able to ascertain, been available for the purpose of determining the relative mortality of the various districts divided in such a manner as to show the comparative health of the very different health districts prevailing in rich and poor districts. These statistics were printed in a tabular form, and were presented at the meeting, and have had therefore a great influence on the public mind, and have fallen into the hands of sanitarians.

tarians and statesmen, who have quoted them freely and appeared to consider them of some value as a ground for legislation. Mr. Gladstone and Sir Wm. Harcourt have in their places in Parliament employed some of the statistics here set out, and I find that they have been quoted at the recent conferences at the International Health Exhibition. I have, on request, furnished copies of the tables to various correspondents, who have since communicated with me, but finding that they are likely to be frequently discussed, and that their more extended publication may possibly be of some public value, I think it well to print them here. I may add that it is my intention from time to time to make a similar periodical analysis of the mortality of the healthy and unhealthy districts of London and publish the tables, and I shall be very glad to receive any suggestion from correspondents which may either further test the value of this mode of tabulation, or add to the information which they are capable of affording. The death-rates in the accompanying tables have all been corrected by the rateable distribution of deaths occurring in public institutions; without some such distribution the uncorrected death-rate of any locality is comparatively worthless.

Mortality Statistics of Healthy and Unhealthy Districts of London.

The average annual deaths in the unhealthy districts, 1880-2, were 7,968; if the healthy districts death-rate had prevailed in the unhealthy districts, the deaths would have been only 4,711, or 3,257 a year fewer than they actually were. This loss of life, according to the estimate of the minimum value of the population (men, women, and children) in 1891, would represent an annual money loss of £1,000,000, the authority there being two for every disabled person, the death-rate, and the assumption that the men aged between 15 and 25 were the most valuable. If, however, the average value of the population be taken, the annual loss from sickness in these unhealthy districts may be estimated at £71,570, making in all an annual loss of £89,437, caused by the excess of mortality in these twenty districts.

As a whole of London, the deaths would have been annually 23,407 less than they were had the healthy districts death-rate prevailed in the unhealthy districts. Applying Dr. Farr's estimates of cost of death and sickness, the annual loss in London is estimated at £4,236,054.

As a whole of London, the deaths would have been annually 23,407 less than they were had the healthy districts death-rate prevailed at Metropolis, applying Dr. Farr's estimates of cost of death and sickness, the annual loss in London is estimated at £4,236,054.

THE SANITARY RECORD.

AUGUST 15, 1884.

The Editor will be glad to receive, with a view to publication, announcements of meetings, reports of proceedings, and abstracts or originals of papers read before the members of any sanitary or kindred association.

THE PROVISION OF MEDICAL ATTENDANCE IN CASE OF EPIDEMICS.

THE spread of cholera in Europe, and the possibility of its introduction into this country, has attracted attention to the means which we have available for combatting that and other epidemic diseases. Sanitary arrangements are useful for preventing the outbreak of disease, but cases may occur when persons are attacked notwithstanding every precaution, and medical assistance may become necessary. If members of the well-to-do classes are attacked, they would probably call in their own doctor, and be attended in the same way, whatever was the disease from which they suffered; and pauper patients have the same right to medical attendance if they are victims of an epidemic as when they suffer from ordinary diseases. But in case of epidemics it is specially important for the well-being of the community that medical assistance should be promptly rendered to all who may need it, and it is well to point out the means by which such assistance ought to be provided.

Under the provisions of the Public Health Act, 1875, which for this purpose is applicable to the whole of England, the Local Government Board may make regulations, amongst other things, 'for the provision of medical aid and accommodation, for promotion of cleansing, ventilation, and disinfection, and for guarding against the spread of disease.' The local authority of the district within which such regulations are in force is bound to superintend and see to their execution, and 'to appoint and pay such medical or other officers and persons, and do and provide all such acts, matters, and things as may be necessary for mitigating any such disease.' The expense of carrying this out must in the first instance be defrayed out of the rates, though in some cases the local authority may be able to recover some part of it from the individuals on whose behalf it has been incurred. In case of hospital accommodation, the Act expressly provides that expenses incurred by a local authority in maintaining a patient in a hospital shall be deemed a debt due from the patient to the local authority, and such expenses may be recovered in a court of law. The charges for medical attendance in ordinary cases can be recovered by a medical man from the person who has employed him to attend, as the law ordinarily implies a contract to pay by the person who calls him in. Such a contract may, however, in some cases be not proved, as recently a gentleman, who had called in a medical man to aid someone whom he saw suddenly taken ill in church, successfully maintained that he had made no contract to pay for the services then rendered. And

medical men may sometimes be—though we believe they rarely are—reluctant to attend cases where they think their remuneration is doubtful. If the services are rendered on the requisition of the local authority, a medical man may feel safe about getting his payment either from the patient or out of the rates, and thus it is to be hoped that there will be no delay in attending to cases of dangerous disease, through any doubt as to payment being secure. In the not improbable case of cholera or any similar disease making its appearance in a ship which enters an English port, the charges for medical attendance on board the vessel, together with any reasonable expenses for the treatment of the sick, are made payable by the captain of the vessel on behalf of the owners. These charges may be recovered summarily, so that there need be no delay in enforcing payment. A case occurred a few years ago which went ultimately to the Court of Appeal, where it was decided that a local authority may make a valid contract to pay a medical man for attending to patients during an epidemic, without observing the formalities which are required by law for the ordinary contracts of corporate bodies. A verbal order to attend, given by a duly authorized member of a local authority, is a sufficient contract to render the authority liable to pay for the medical man's services. As we have seen such services may properly be paid for out of the rates, irrespective of the question of the patient being a pauper, and the question as to who is ultimately liable to pay is one with which the medical man at the time he is called in need not concern himself. Parliament has rightly considered that in case of epidemics it is most important to have medical attendance promptly available for all who need it, and has imposed on the local authorities the liability of providing such attendance, where it may be needed, and has not imposed on them any restrictions which would delay or prevent the employment of a medical man where his services are needed.

THE Local Government Board has appointed Mr. E. G. Ballard to be an inspector, and Mr. Adrian Blakie, D.Sc., to be a sub-inspector under the Alkali, &c., Works Regulation Act, 1881.

SANITARY INSTITUTE OF GREAT BRITAIN.—At the anniversary meeting held at the Royal Institution, Albemarle Street, on Thursday, July 10, the Right Hon. Earl Fortescue in the chair, an address was delivered by Dr. H. C. Bartlett, entitled 'Some of the Present Aspects of Practical Sanitation,' and the medals and certificates were presented to the successful exhibitors at the exhibition held at Glasgow in September 1883. At the close of the address the chairman proposed a vote of thanks to Dr. Bartlett, which was seconded by R. B. Grantham, M.Inst.C.E., and a vote of thanks to the Right Hon. Earl Fortescue for presiding, was moved by Dr. A. Carpenter, and seconded by Professor de Chamisso, M.D., F.R.S.

VENTILATION OF PUBLIC BUILDINGS.—Messrs. Robert Boyle & Son, 64 Holborn Viaduct and Glasgow, have recently applied their system of ventilation to the Hall Quarters of the Honourable Artillery Company, Finsbury; Liberal Club, Sheffield; Burton Club, Burton-on-Trent; County Hall, Menai Bridge; Franciscan Convent, Bridgewater; New Lecture Hall, Newcastle-on-Tyne; Bromley and Beckenham Joint Hospital; New Public Baths, Lewisham; London and County Bank; St. Austell Union; Hull Workhouse, Hull; New Workhouse, Wandsworth; Richmond Union, Surrey; Haswell Police Station; New Police Station, Mitcham; Her Majesty's Prison, Leicester; and Her Majesty's Prison, Manchester.

LONDON WATER SUPPLY.

to be deplored that the merits of the as to the London water companies, and ey supply, should be obscured by the professional antipathies and disagreeow rage around the question. Granted ility of the water is rendered infinitely it might be by the carelessness of orage in cisterns, the inquiry whether olluted Thames can be regarded as a r the potable water of some millions of ts of but one answer. Yet we are in- water companies and their professional o believe that really and truly the n volume of the water in the Thames, omplaints that have been made about in the papers, do not affect in the least s a beverage; and that, in point of fact, re exceptionally lucky in having so re a supply to drink.

f the possible introduction of cholera , and the desire expressed by the medical officers of health for the recti- fects (if any) in the water supply of the and particularly for watchfulness over s and mains of the water companies, a on was recently addressed by Sir on to each of the eight companies on specially asking whether they had any port, and whether they could suggest, in heir customary precautions for ensuring heir water supplies, any improvements l precautions capable of being taken resent summer. The replies received ompanies are reproduced in the last e water examiner, and will be read with ty and not a little scepticism. It was e expected that the companies would wn nests by reporting defects in the

Sir Francis Bolton ingenuously sup- ordingly, we find that with one voice heir arrangements as the most perfect be devised, and as to improvements, e be impossible. The companies are ver, in their condemnation of house- all classes in not looking after their they ought. A variety of pains and e suggested as fitting punishments for o not keep their cisterns in a condition : extraordinarily pure and lavish supply igh the companies bountifully bestow. rovements, the vast filtering beds, the ply, the perennial analyses, the hydrants, of it, are set at nought by the neglect of lder to clean out his cistern with due id frequency. No doubt domestic water re very often sadly neglected, but is not d harping upon the carelessness of the a little suspicious, with our knowledge ions and neglects of the companies?

I have thought that the revelations of Department of the Local Government the fallacies of the results declared by its ought by this time to have exploded its based upon the largeness or small- ven bottle of water of the decimal frac- ain of some particular chemical com- en a sample of water, to which has been preciable quantity of the excreta from a ring from typhoid fever, gives, in the

hands of an eminent chemist, results which would place it in his first class of waters, those, namely, of 'extraordinary organic purity'; it is time to consider how far we are justified in relying upon laboratory inferences rather than upon the evidence of the senses. Yet Messrs. Crookes, Odling, and Tidy, who are paid by the London water companies to make to the President of the Local Government reports which he does not want, and refuses to recognise, would apparently have us believe that the Thames is still the same pellucid and silvern stream whose merits the Elizabethan poets were wont to sing.

These gentlemen report that during the first half of 1884 they examined 1,071 samples drawn from the mains of the seven companies taking their supply from the Thames and the Lea, and have been able to register these many samples as being, without a single exception, clear, bright, and efficiently filtered. Judged by the eye, they had all of them the further claim to be described as being, even when in considerable bulk, colourless. Subjected to more exact examination in this particular, their degree of brownish tint proved to be exceedingly low, so as in no case to preponderate over the proper blue tint of the water. The whole of the 1,071 samples were further examined for organic matter by the permanganate process, and for dissolved oxygen by the Schutzenberger process, with similar satisfactory results. As regards the quantities of organic carbon, and consequently of organic matter, present in the Thames-derived samples, the mean result for January, exceptionally low for this season of the year, was '118 part of organic carbon in 100,000 parts of water. The mean result for February was '140 part, for March '165 part, for April '139 part, for May '104 part, and for June '114 part of organic carbon in 100,000 parts of the water; while the highest result furnished by any single sample examined during the last two months was '129 part, equivalent to about a quarter of a grain of organic matter per gallon.

The Report of the Royal Commission on Water Supply is quoted to show that a minute proportion of organic matter, variable in amount with season, is a normal constituent of river water, and it is argued that there is no reason whatever to consider this proportion of natural organic matter as in any way prejudicial to health; and that there is absolutely no chemical evidence to indicate that the small proportion of organic matter present in the water supply of London is different, either in quantity or kind, from the natural organic matter of the river, as met with, for instance, at Lechdale, 120 miles above the intake of the companies. Still, in view of the importance which is attached, unwarrantably the reporters think, to the not inconsiderable variations in the proportion of organic matter present in the London supply, the consolatory remark is added that at periods of summer heat and drought like the present the natural agencies at work to keep down the proportion of organic matter existing in the water of the river are at their maximum of activity. 'It results in this way, that the water supply of London is at its best just at those seasons, like the present, when any failure in the quality of the supply might be considered likely to be of exceptionally serious import.' On reading this report one is tempted to repeat the inquiry, 'Can these things be?'

THE Corporation of Newcastle have agreed to erect a refuse destructor of twelve cells at Byker Hill, at an estimated cost of 7,000*l*.

REPORT OF THE METROPOLITAN BOARD OF WORKS FOR 1883.

THE work of the Metropolitan Board of Works increases every year, and, in view of the probability of an alteration in the local government of London, this report is of unusual value, as it shows the vastness of the labour that will be required from the proposed new Municipality. The Board has charge chiefly of matters affecting the metropolis as a whole, leaving those which are of a local character, such as scavenging, providing and maintaining sewers, supervising the construction of house drainage, and the general sanitation of the various parishes, to the vestries and district boards. The number of meetings of the Board and committees during the year amounted to 379, of which 104 were meetings of the whole Board, including 59 of the Works Committee and 275 of other committees; an immense labour for 46 persons to perform.

The supplementary main drainage works decided upon in 1879 consisted chiefly of storm overflows for various parts of the metropolis, so as to prevent floodings of various low-lying districts; but, judging from accounts lately received from places in the vicinity of the Lea, the scheme has not been successful so far as that part of London is concerned. The metropolitan improvements during the year are fully stated, and the relaxation granted as to the number of artisans' and labourers' dwellings, which have to be provided when old houses are pulled down, is especially referred to, as enabling the Board to carry out several long delayed improvements. Amongst these may be mentioned the new street from Tottenham Court Road to Charing Cross; the removal of the houses in unhealthy areas in Limehouse, Lambeth, St. George's in the East, Greenwich, Whitechapel, and other places. As regards several representations which the Board have received respecting blocks or groups of houses that were deemed to be unfit for human habitation, they were referred back to the vestries of the parishes from which they were sent, because the Board consider they are required to take action only when 'a complete re-arrangement of the area is required, including the opening up and widening of the streets and passages which intersect it, so as to bring in more light and air.' The cost therefore of the minor improvements necessary for providing sanitary dwellings for the poor will fall in future upon the parishes in which these small areas exist, and not upon the whole of London. This is a very important decision, especially as regards the poorer metropolitan parishes, and may have to be reconsidered.

The report refers at some length to the bridges over the Thames, nine of which are vested in the Board, three are under the control of the Corporation, and one only—viz. Westminster—was built and is maintained at the cost of the State. The question of providing additional means of communication between the north and south sides of the river below London Bridge is especially dwelt upon. The engineer to the Board brought up in 1883 a scheme for a new bridge and two tunnels, at an estimated cost of five millions sterling, which was abandoned, so far as the bridge is concerned, by the refusal of the Government to support a Bill for the extension of the coal and wine dues. The Board seem to have acted wisely in abandoning the scheme, as in 1889, when these dues will cease to be payable, the rates will be considerably increased. The chief objections

by the Treasury to continuing the duties be that the debt due by the Board would very formidable proportions by the borrow sum and of others, for other improvements appeared to 'my lords' as not sufficiently justify a continuance of a tax which adds 7 to the cost of coals. The parks, commons, spaces are also referred to, and, as they 1,769 acres, the cost of their purchase, 484, of their maintenance is by no means to be. The action taken by the Board to close lators of the District Railway is stated as le the decisions arrived at by the Committees by Parliament are considered to be contrar the public has reason to expect, and by 1 satisfactory to the Board after the large ex they had incurred.

Under the head of gas supply we are that the limit for ammonia is now 4 grai cubic feet of gas, and of sulphur from April ber 17 grains, whilst from October to maximum is to be 22 grains per 100 cu These limits have not been exceeded on cation by any of the companies to an ext cient to justify any adverse action being the Board. The gas is required to have ing power of sixteen candles when cons the rate of five cubic feet per hour, but the 1 statement is made that there is some room whether in districts on the north side of remote from any testing place, the gas is as good quality as in districts where the gas The Board has suggested, therefore, that a testing-places should be provided. The 1 the working of the Cattle Diseases Act are fi tioned, and it appears that 16,523 anim found in premises where the stock were with contagious diseases, and of these 2, affected with one or other of these disease were killed, 1,422 removed, and only 39 di injury that might have resulted from the u diseased meat and of the milk of the affec certainly justify the cost—nearly 3,800/-for out this Act. The examination of the Londo milk-shops, cowsheds, and slaughter-houses actively carried on, as 26,386 visits were pa 1,121 cowsheds, 231 dairies, 1,941 milk-sh the 809 slaughter-houses that have been p. the registration list. Two new slaughter-hou been licensed during the year, and 44 have t up, so that the gradual closing of the smal most unsuitable slaughter-houses is rapidly ing, the number when the Act was passe been 1,429. The Infant Life Protection Ac been a success, and its working during the not been much more satisfactory than befor chiefly arises from the difficulty of ascertai persons who are engaged in baby farm as many as 280 infants were found in unnr houses. In six cases only was the Act have been infringed, and only two prosecuti instituted. There are only 37 registered b London. The details as to the supervision c and buildings, including theatres, as well as other matters, are fully set out, but the space taken up prohibits even their enumeration.

THE Corporation of Newcastle have resolved to the Local Government Board for leave to borrow to defray the cost of the proposed hospital for diseases to be erected at Heaton, according to t already approved by the Council.

NOTES OF THE MONTH.

LOCAL APPRECIATION OF INFECTIOUS HOSPITALS.

Issue of April last (see vol. v., new series, p. 498) recorded an instance of the growing appreciation of usefulness of infectious hospitals, especially with reference to the admission and treatment of children. A gratifying proof of this is afforded by Mr. Harper who, in a recent report on the health of the rural district of Bath, observes that he has been very busy in persuading parents to send their children to the hospital. In fact, it appears to be in vogue to the extent that the small children think it a disgrace to be sent home, and often cry to be taken to the hospital.

Mr. Harper speaks in high terms of praise of the kindness shown by the hospital authorities, and adds that this, together with the extension of the hospital as to the nature of infection, will tend to make the public more anxious to obtain the advantage of isolation. Even now the patients are not taken from the poorer classes, but to a certain extent from those who are able to make some contribution towards the expenses of their maintenance in the hospital. In addition to verifying, in a considerable degree, the information collected by the hospital when investigating the subject, Mr. Harper's experience proves that even during the last few years a very considerable improvement has taken place in the attitude of the general public towards statutory hospitals.

INSTRUCTIONS FOR THE REARING OF INFANTS.

The object of combatting the ignorance displayed by parents in the rearing of their offspring, Mr. Cameron has suggested to the Town Council of Huddersfield that they should adopt the plan already in use in several cities at home and abroad of giving to every person registering a birth a small leaflet containing brief directions for the management of infants. He proposes that the first leaflet should contain only information about the feeding and the ventilation of their rooms, and a second leaflet containing brief directions for the prevention of infectious diseases. On the approval of this, a separate leaflet on the treatment of measles and whooping-cough should be prepared and distributed from the health office. Dr. Cameron believes that these leaflets would be of essential service to numerous unintelligent but inexperienced mothers, and he highly recommends the suggestion to his authorities. The plan, which is deserving of every commendation, has been tried with excellent results in parts of the country, and there is no reason to suppose that its adoption in Huddersfield should not be successful.

OFFICIAL VIEWS AS TO CHOLERA.

In view of the further indicating the true lines of preventive action which should be followed in the case of cholera reaching these shores, Dr. Buchanan, medical officer of the Local Government, has prepared a preliminary report on the subject which is accompanied with extracts from reports made by himself and other medical inspectors during the years 1865-66 and 1873. In Dr. Buchanan's view, the reprints are intended to serve a double purpose. The extracts from the reports of Mr.

Simon exhibit, at greater length than in a memorandum, the doctrines concerning cholera in Europe which have been continuously held by the principal medical advisers of the English Government. Dr. Buchanan believes that they are commanding more and always more adherents among sanitary authorities on the Continent, though hitherto they have not obtained sufficient recognition in practical effort. The extracts from the reports of medical inspectors on the other hand are primarily intended for the assistance of those who may have to deal with local conditions provocative of cholera or with any outbreak of the disease in England. Both series of extracts will at the present moment be of service as indicating the true lines of preventive action against the disease which is now threatening Europe.

For public use in this country the all-important principle of cholera prevention is, that 'cholera derives all its epidemic destructiveness from filth, and specially from excremental uncleanness,' and 'the local conditions of safety are, above all, these two: (1) that by appropriate structural works all the excremental produce of the population shall be so promptly and so thoroughly removed, that the inhabited place in its air and soil shall be absolutely without faecal impurities; and (2) that the water supply of the population shall be derived from such sources and conveyed in such channels that its contamination by excrement is impossible.'

These are the words of Mr. Simon, written nearly twenty years ago and embodying the experience of nearly twenty previous years. They were written when local sanitary authorities in England had seldom begun their work; when port sanitary authorities had made no provision for dealing with imported disease; and when special orders in face of cholera were requisite in order to give such powers as those authorities have now long possessed as standing defences against all infectious diseases. It is certain that in proportion as the sanitary authorities of England have done their regular work, and exercised their ordinary powers for the protection of the public health, the country has now even less to fear from cholera than in former invasions of Europe by the disease. The extracts from reports of medical inspectors relate to certain local appearances of cholera in England during the years 1865-66. The specimen reports relate to occurrences of cholera at Theydon-Bois, in Southampton, on Irish mail steamers, at a village near Bristol, and among migrating foreigners passing through English ports. Thus they show cholera making its appearance under a variety of circumstances, and they afford some instructive instances, first of the customary, though sometimes obscure, relationship of cholera with foul water or air; secondly of the way in which the disease has been restricted to the locality of its first appearance and has rapidly become extinguished there.

ALLEGED INJURY BY VACCINATION.

THE anti-vaccinators make up in misdirected energy what they lack in numbers. Their latest attempt is an endeavour to make capital out of certain words used in the National Health Society's useful leaflet of 'Facts concerning Vaccination,' in order to make appear that the Local Government Board was stultifying itself by approving language which Dr. Cory's case traversed. Mr. George Russell, however, was able without difficulty to meet Mr. Hopwood's astute

inquiries on the subject. He pointed to the words of the pamphlet, 'that with due care in the performance of the operation no risk of any injurious effects from it need be feared,' and that such mischief as the communication of a foul disease by vaccination 'could only happen through the most gross and culpable carelessness on the part of the vaccinator.' These statements were in no way inconsistent with the report of the medical experts respecting Dr. Cory's case. The committee reported expressly that 'the infants from whom Dr. Cory took lymph for his experiments on his own arm were in such a condition of obvious syphilitic disease as would certainly have precluded their use as vaccinifers by even an inconsiderate and reckless vaccinator. Indeed, they were selected by Dr. Cory for his self-vaccination because they were unquestionable syphilitic cases.' It is a rule of practice in the profession not to use in vaccination lymph taken from a child in whom there is any suspicion whatever of syphilitic taint, or indeed in whom there is any skin disease, although of a character known to be harmless, and the observance of this professional rule is strictly enjoined by the Local Government Board in its instructions to public vaccinators throughout the country. The Board saw no reason to alter their view with regard to the pamphlet in question, which had been revised by their medical officer, and had been recommended for house-to-house distribution.

A YOUTHFUL SANITARIAN.

DR. H. C. BARTLETT, F.C.S., in his address on 'Some of the Present Aspects of Practical Sanitation,' delivered at the anniversary meeting of the Sanitary Institute of Great Britain, on July 10, refers to the written examination of May Austin, aged 13, Standard VII., who sends in a paper from the Rea Street Board School, Birmingham, shown in the School Board exhibit at the International Health Exhibition. Dr. Bartlett goes on to declare that in answer to the question 'What special points would you think of in choosing a house?' the answer was 'Dryness, light, good air, good water, and good drainage.' In delineating these 'principal points,' the descriptions are so terse and full, so complete, and leave out so little of what is essential, that unless the whole examination and teaching is the cut-and-dried result of mere *memoria technica*, nothing could be more satisfactory. If May Austin can reply on paper equally well to half a dozen more questions coming equally within the scope of our own examinations, and pass a by no means more difficult *vivâ voce*, he feels bound to admit to himself that he, as an examiner of the Sanitary Institute, must pass that very clever little girl—certainly as a sanitary inspector, and perhaps as a local surveyor.

TYPHOID FEVER IN WORCESTER.

In his last report on the health of Worcester, Dr. Strange discusses the question how it is that, with the causes of typhoid fever so well ascertained, the disease still prevails in a town supposed to be drained and scavenged like Worcester. It is, he believes, that the draining and scavenging are imperfect. The sewers are defective, there being a frequent issue of sewer-gas from the gullies. It was to remedy this defect that eighty new ventilators were fixed a short time ago. But the chief fault

lies in the house drains and closets. Many of the house drains are badly laid, more especially in newly-erected cottages. The closets, sanitary or water, are constantly getting out of order, chiefly through the negligence of those who use them; and, if it were not that they are always placed out of doors in cottage property, the consequences would be much more serious than they now are. Moreover, water-closets of an old-fashioned construction and imperfect action are still to be found in the better class of houses, and, consequently, typhoid is as frequent in them as in the poorest cottages. The large old-fashioned privy cess-pits, some of which still remain, are also answerable for their share of typhoid. In regard to the purity of the water supply of his district, Dr. Strange observes that in so porous a soil as that of Worcester, percolation of foul matters may take place along great distances underground. The discharges from typhoid patients are often thrown into drains, or buried lightly in the soil, without efficient disinfection. These may, and doubtless do sometimes, gain entrance into the wells. And this is all the more probable because some years ago (1866), when well-water was largely used, hundreds of wells were found to be terribly polluted with sewage matter. Dr. Strange reminds his authority that a prevalence of typhoid reflects discredit upon the sanitary arrangements of the town, and he appends a list of practical suggestions, which, if carried out, would soon bring about the removal of this blot. The authority should bear in mind Mr. Simon's opinion, that 'present knowledge seems very positively to say, that the degree and extent in which enteric fever shall remain unexterminated from England will expose the degree and extent in which sanitary administration had failed in rudimentary duties.'

ISOLATION PROVISION FOR SCARLATINA.

In commenting on the prevalence and fatality of scarlet fever in Northampton during the past year, Mr. Lee Cogan again draws the serious attention of the Town Council to the fact that, in the absence of means for hospital isolation, efforts to cope with the disease, with the object of checking its propagation, were rendered, if not positively inert, at least, comparatively speaking, ineffective. As Mr. Cogan points out, infectious hospitals afford advantages beneficial both to the sufferers and also to the community at large. The circumstances under which these patients can be treated in well conducted institutions are manifestly in every respect immeasurably more favourable for them than when treated in their own homes. The public by the removal of infected persons is preserved from the dangers of infection. The experience of almost every town possessing an infectious hospital testifies to the benefit to the public health afforded by such institutions, and Mr. Cogan anticipates that before long every town of any size throughout the country will see the absolute necessity of providing itself with a sanatorium for the disposal of its infectious sick. It is, indeed, for cases of scarlatina that, as Dr. Thorne has emphasised in his report on the subject, isolation is most constantly and most urgently needed. The mortality it occasions exceeds that of any other communicable fever prevalent in the country; it is highly infectious, and there are no effectual means apart from its isolation by which its spread can be stayed. It is to be

oped that the Town Council of Northampton, so are responsible for a population of nearly 10,000 persons, will no longer delay the erection of suitable hospital, the more so now that the extension of cholera to this country is by no means an unlikely contingency.

THE DELANCEY FEVER HOSPITAL.

THE report recently presented on the work of the Delancey Fever Hospital during the first decade of its existence affords abundant evidence of the benefits which accrue to a district provided with properly equipped isolation accommodation. This is evidenced in a striking way by the immunity which Meltonham enjoys from small-pox. Although during the past ten years the disease has gained a footing in the town on twenty separate occasions, not a solitary case has remained in the district over forty-eight hours, nor has the disease in any instance spread beyond the family it entered. These results have undoubtedly been brought about by the prompt and energetic measures which have in each case been adopted for the isolation of the sick, for thorough disinfection of the premises, and the inoculation of the inmates. Notwithstanding that there was a considerable prevalence of scarlet fever in some of the lower parts of the town, 59 cases having been reported during 1883, but five persons only were sent to the hospital by the Town Council, and two by the Board of Guardians. As the committee of the hospital observe, these numbers tell their own tale of cases allowed to go through the house at home, often in crowded localities, with the absolute certainty of widening the circle of infection, and so defeating the very objects for which the institution was founded. It is to be hoped that in future the local authorities will avail themselves more extensively of the accommodation afforded by the hospital, and this will doubtless be accelerated by a material reduction which has recently been made in the scale of charges. Dr. W. R. Smith, who appears to have bestowed much care on the working of the hospital, notes that the average age of the cases of scarlet fever was 15 years, and the average length of stay a little over forty-three days. All the patients were discharged cured. During the year the erection of a small-pox laundry and wash-house was completed, and the hospital was provided with a self-acting disinfecting apparatus.

WHAT IS A DWELLING-HOUSE?

A GOOD deal of somewhat heated controversy arose in the House of Commons on May 27 with reference to a definition suggested by Sir Edward Watkin that a 'household qualification' and 'a dwelling-house qualification' should mean respectively a tenement containing not less than two habitable apartments. The honourable baronet, remarking that the dwellings conferring the franchise ought to be dwellings for Christian people, argued that the class in which fathers, mothers, and children of both sexes lived in the same room could not be regarded as capable citizens, and were unfitted, therefore, for the giving of a vote. This view was disputed by Mr. Edmondstone, who brought his Midlothian experience to bear upon the question, and Sir Charles Dilke, whose position as Chairman of the Royal Commission on the Homes of the Poor has convinced him that the policy of the one-roomed population of the country

are 'very capable citizens indeed.' To the argument of this point we shall not, of course, address ourselves; but there is one complaint made by quite a number of members in the course of the debate which has a wider significance, and that is the absence of any definition as to what constitutes a dwelling-house. The late Master of the Rolls, one of the acutest intellects the world has ever seen, in an appeal case with reference to the term 'dwelling-house,' said 'What that means nobody can say.' And he went on to observe, 'I have tried, and tried in vain, to frame an exhaustive definition which is satisfactory to my own mind.' Where so eminent a lawyer has failed, it would, of course, be presumptuous of us to offer an opinion; but may we suggest that opportunity should be taken in some way or other to settle the question which has exercised so many minds in Parliament and elsewhere. The Franchise Bill appears to afford an excellent opportunity of doing this, and it is after all in connection with the voters' register that the wrangles about the meaning of the term chiefly arise.

DIRTY TENANTS.

THE Gateshead Sanitary Authority have instructed their inspector to take vigorous action against those people who habitually keep their houses in a filthy condition, to the danger of the public health. Mr. Jones, the inspector, has accordingly summoned several persons before the magistrates, as it is beyond doubt that much of the disease in the borough is caused entirely by the filthy habits of such people. On the 13th ult. Thomas Dickson, of 4 Chapel Street, Gateshead, was charged with having his house in an indescribably filthy condition. The defendant did not appear, but his wife said that they had six children in the house, and none were healthier. The magistrates ordered the house to be thoroughly cleansed at once, and adjourned the case for a week. Their decision would depend upon how their orders were complied with. The Corporation of Newcastle, at their last meeting, acting under Sect. 90 of the Public Health Act of 1875, passed some by-laws for the better regulation of tenemented property, which will enable them to deal more effectually with dirty tenants and refractory landlords. The motion was strongly opposed, on the plea that the terms of by-laws were not publicly well known, and that they would probably be infringed unwittingly. Mr. Annan, as a matter of justice, gave notice that he would move at the next meeting that they be rescinded.

FOREIGN SANITARY EXHIBITS AT THE HEALTH EXHIBITION.

VISITORS to the Health Exhibition, if they will take the trouble to examine some of the examples shown by foreign exhibitors, will be able to make instructive comparisons between these and some of the exhibits of our own country. From a strictly sanitary point perhaps they will not be able to do so, as the foreign sections generally seem to have ignored the question of drainage on any scientific principle, and this perhaps is not to be wondered at, as any one having had much experience of foreign hotels and houses must have come to the conclusion that both science and principle are entirely wanting. In the Belgian Section they will see that the sanitary arrangements

of some of their large schools are more or less illustrated, but that, however, on lines which we should scarcely care to follow. A few efforts are also shown as regards housing the poor, although on a small scale, but one example on the building society principle goes carefully into the cost, and gives the results, which certainly seem to be very satisfactory, and might be in certain circumstances developed more fully in this country, where the want of organisation is a great hindrance to the movement. In the French Section, however, some attempts at sanitation may be noticed; an apparatus for disinfecting clothing and bedding by means of hot air and fumigation is illustrated, and several hygienic works and brochures are given; but these we are afraid are special cases, and the majority of Frenchmen have not yet awakened to the broad principles which are rapidly becoming so general here and in America. Some instances of housing the poor, also on a small scale, are shown, but the illustrations scarcely lead us to suppose that the sanitary requirements are met in the way that we are accustomed to.

SLAUGHTER-HOUSE REFORM.

A LITTLE tract with the above title reaches us from Coventry. Some particulars relating to the Public Abattoir movement having been supplied to the 'Coventry Society for the Prevention of Cruelty to Animals,' the committee thought it advisable to lay the information before the public, together with some extracts from the reports of various societies, in the hope that it might help forward the provision of improved accommodation for slaughtering in Coventry. We heartily wish the compilers of the pamphlet all success. Coventry, like so many other important towns, has no public slaughter-house, and the slaughtering is done in fifty-three private slaughter-houses, the condition of many of which is far from satisfactory from a sanitary point of view, many of them being 'small, situate in the midst of crowded localities, approachable up entries and passages, in close proximity to dwelling-houses, and in one or two cases are to the front of the street, where the public may witness the slaughtering.' We are pleased to see that organisations for the repression of cruelty to animals are taking this matter up. Those who desire the efficient inspection of all carcasses intended for the food of man, and that killing shall be done under wholesome conditions, will find useful allies in those who are working for the prevention of cruelty. The general provision of public slaughter-houses, and requiring that all killing and dressing be done therein, is the only way to prevent cruelty, no less than the only way to stop the trade in diseased meat.

EMIGRATION

By the issue of the emigration return for the month of June we are enabled to summarise the returns for the first six months of this year. It appears that during this period there has been a very marked decline in emigration from the United Kingdom. During the first half of 1884 the total number of emigrants from the various ports where emigration officers are stationed was 165,594, of which 129,129 were of British origin (including 71,088 English, 12,040 Scotch, and 46,001 Irish), 35,116 foreigners, and 1,049 whose nationality was not distinguished. Compared with the corresponding period of the

preceding year 1883, the number of emigrants for each division of the United Kingdom, as well as the number of foreigners, showed a decrease, the largest proportional decline being in the Irish emigrants. In British emigration the decline amounted to 20 per cent. among the English, 27 among the Scotch, and no less than 38 among the Irish. The numbers of British emigrants, which during the first six months of the three years 1881-83, were 115,793, 148,730, and 178,955 respectively, declined, as before stated, during the first half of this year to 129,129, or as much as 28 per cent. Of these 129,129 emigrants of British origin, 82,276 sailed for the United States, 19,476 for British North America, 22,799 for Australia, and 4,578 for all other places. Compared with the corresponding period of 1883 the emigration to the United States declined 27 per cent.; to British North America, 30 per cent.; to Australia, 25 per cent.; and to all other places 25 per cent. With reference to the proportion of the population of the three divisions of the United Kingdom who emigrated during the first six months of the current year, it may be noted that of each million of their estimated populations 2,657 English, 3,138 Scotch, and 9,296 Irish, emigrated. These proportions showed a marked decline from those recorded in the corresponding period of 1883, when they were 3,340, 4,358, and 14,326 respectively.

SANITARY ARRANGEMENTS IN THE CITY.

At a recent meeting of the City Commissioners of Sewers it was moved, 'that in all instances where new houses were being erected the Commissioners of Sewers should place themselves in communication with the building or other owner, and treat with him or them for the construction of a proper ventilating shaft in the chimney-breasts or party or other walls for the purpose of ventilating the sewers, carrying the ventilating shafts well above all adjoining roofs. At first sight this may appear to be a rather startling suggestion, to bring the foul gases from the sewer through the house. At present the sewers under the public roads are ventilated by a number of iron gratings placed in the centre of the roads and communicating by means of brick shafts with the sewers, these gratings serving both as inlets of fresh air and outlets for the foul air. But it must certainly strike anyone that the idea of discharging the gases at the level of the roadway is rather a primitive one, and not in keeping with the advanced views in other directions, and it would undoubtedly be a great improvement to disperse the foul air above the roofs of the houses. If every house in a road were provided with a 4-inch ventilating pipe attached to the branch drain leading from the sewer, the gratings in the roadway would then become inlets of fresh air, and the discharge of foul air being so thoroughly subdivided, and also effected above the houses, the arrangement would then become as safe as could be well imagined. The ordinary suggestion is that the ventilating pipes should be carried up *outside* the houses. The advantage of placing the pipes *inside* is that they would thus be kept warmer and the up-draught be stronger. It would be objected at once that in case of a single joint of this pipe becoming defective the house would be poisoned by gas from a great length of sewer, but in new houses this danger might be averted by placing the pipe in a carefully and specially arranged flue, so that any escape of gas

would be confined to the flue, and would find its exit in the ordinary way. If we mistake not, this system has to a limited extent been carried out at Gloucester, under the direction of the city surveyor, but in London especially there would be many difficulties in construction and other points, which must for some time to come prevent its adoption from becoming general, how desirable soever it may be.

HOW TO PREVENT AND OPPOSE THE CHOLERA.

THE National Health Society have issued a circular letter to sanitary authorities, stating that in view of the spread of cholera in France, and of the possibility that the disease may be imported into this country, it appears to be very important that householders generally should understand the precautions which they must individually adopt if the progress of the disease—when it has once gained a footing here—is to be checked. In these circumstances the society has prepared a memorandum, couched in plain and simple language, explaining 'How to Prevent and Oppose the Cholera.' The society suggests that this pamphlet might very usefully be distributed from house to house in each district by the officers of the sanitary staff. With the object of encouraging as far as possible the taking of precautions against the invasion of cholera the society are prepared to supply copies at the cost of printing—viz., 1*l.* 1*s.* per 1,000, and will on request give instructions for the filling in of certain blanks on the last page, with the names of the local medical officer of health and inspector of nuisances, without further charge, provided that no less than 5,000 copies are ordered. The memorandum contains a variety of useful instructions as to the precautions to be observed to keep the cholera away, and to prevent its spread if it should come. Its universal distribution throughout the country would therefore be a great advantage, and it is to be hoped that local authorities may see fit to incur the small expense which the purchase of a few thousand copies would entail. It should be added in this connection that the pamphlet, being a copyright publication, cannot be reprinted without the assent of the society.

VACCINATION *v.* VACILLATION.

THE Guardians of Dewsbury appear to be sincerely desirous of emulating the doughty deeds of the Keighley guardians of happy memory, and of spending a period of seclusion at York Castle in the sacred cause of anti-vaccination, to be welcomed back at its termination with banners and bands of music. It is perfectly idle for the guardians to pretend that they are anxious to carry out the vaccination laws under proper safeguards. Their whole action shows them to be possessed with the demon of incurable wrong-headedness. They have trifled with the law and the Local Government Board long enough. With their specious pleas of lack of proper candidates, and of desire that the vaccinator shall give a guarantee against ill-effects arising from vaccination, they have frittered away something like twelve months of time, during which the district has remained unprotected from small-pox. It is to be hoped that the guardians will now recognise that, whether they like it or not, the law is more powerful than they, and that if they do not do as the law tells them, what Mr. Baron

Huddleston delicately styles 'very serious consequences' will follow for themselves.

POISONED BY CANNED TOMATOES.—DANGER OF USING A CHLORIDE OF ZINC FLUX.

AN interesting case, in which a whole family were poisoned (fortunately not fatally) by eating canned tomatoes, is reported by Dr. J. G. Johnson, of Brooklyn. A lady, her son and nephew, and three daughters, partook of bread and butter and boiled tomatoes for lunch. About two hours after they were all taken ill with burning pain in the pit of the stomach, intense thirst, dryness of the throat, retching and tenesmus. On the symptoms increasing the mother administered a purge, and the boys, after some hours, were able to throw off the contents of their stomachs, and improved. The mother and daughters grew worse, and by the fourth day the eldest daughter had all the symptoms of severe gastro-enteritis, the abdomen being intensely tender, and she was beginning to sink into a state of coma. The mother and second daughter suffered in the same way, the latter having, in addition, a fiery red eruption from head to foot, accompanied with intolerable itching. The eldest daughter passed into a state of profound coma, from which she could not be aroused, and on the evening of the eighth day she was seized with epileptiform convulsions, which continued with considerable severity till the tenth day, when the bowels began to act, and the patient improved. By this time the other patients were also convalescent. That they were suffering from some irritant poison was evident from the fact that they all sat down to lunch in health, and that all who partook of the lunch were affected. That the poisoning was not caused by the bread and butter was proved by the lady's husband having eaten of it for breakfast and supper with impunity. Dr. Johnson concluded the symptoms were not those which might be expected from the ingestion of over-ripe or spoiled tomatoes, and that if there had been a ferment or poisonous mould present it would have been rendered innocuous, as the tomatoes had been well boiled just before being eaten. Could the vessel used in cooking have introduced a mineral poison? No; the vessel was made of fire-clay with a salt glaze, and had been in use by the family for over a month. The spoon used in stirring was also carefully examined—it was triple plated and unworn. The poison must have been a soluble one, and contained in the tomato juice, for the eldest daughter (who suffered most severely) had not eaten of the solid part, but soaked bread in the juice. Unfortunately the dishes had been washed, and none of the fruit or juice remained for analysis. The symptoms corresponded closely with those of verdigris poisoning, and Dr. Johnson was at first inclined to attribute them to this, as in canning establishments large copper kettles are used, and verdigris frequently forms in them when acid fruits are stewed and allowed to stand. However, on showing a can similar to that used for the tomatoes to a tinsmith a flood of light was thrown upon the case. This man pointed out to Dr. Johnson that the cap was not fastened to the head of the can by a resin amalgam, as the sides were, but that the amalgam was made of muriate of zinc—i.e. pieces of zinc were placed in muriatic acid and dissolved till the acid would no longer attack the zinc, and this liquid was painted into the groove at the head of the can. The cap

was then placed on and held with a clamp, and the soldering iron passed round. Of course the solder held the acid in, and if there happened to be too much acid applied to the groove, then, as the tin expanded with the heat, it would be forced into the can. This appeared to Dr. Johnson to offer a reasonable solution to the problem he had set himself to master—the source and nature of the poison in canned tomatoes, the ingestion of which had so nearly proved fatal. That chloride of zinc was the poisonous agent in these cans is not absolutely proved, but so nearly that Dr. Johnson is more than justified in warning the profession and the public against this new danger, and cautioning purchasers to ‘reject every article of canned food that does not show the line of resin around the edge of the solder of the cap, the same as is seen on the seams at the side of the can.’

LAMB AT THREEPENCE A POUND.

A MAN named Clark, living at Turnham Green, was lately prosecuted by the Fulham Board of Works for exposing for sale in King Street West, Hammersmith, the carcase of a lamb unfit for food of man. Dr. Collier, the medical officer of health for the district, stated that on the evening of the 21st. ult. his attention was drawn to the defendant's stall by a man calling out ‘Lamb, 3d. a pound.’ He went up to the stall and noticed a carcase of lamb, the flesh of which was spotted. He was of opinion that the animal had died of fever, and the meat had been brought before a magistrate and an order to destroy it obtained. Mr. Kisch, who appeared for the defendant, said the meat was Australian, and was so late in the market, through delays in transit, that the defendant had been able to purchase it at an exceptionally cheap rate. It was passed by the port sanitary authority and by the chief inspector of the meat market. Mr. William Wild, Chief inspector of the market, was called, and confirmed Mr. Kisch's statement. The defendant was fined 10s. and 3s. 5s. costs; the magistrate remarking that if it had appeared to him that the defendant knew the meat was bad he would have sent him to prison.

This case affords a good illustration of the unsatisfactory way in which meat is inspected. All meat intended for food of man should be subjected to a careful examination to ascertain if it be sound and free from disease, and the examiner should possess the necessary skill and knowledge. One inspection is sufficient provided it be thorough. As matters are, however, it would appear that meat may run the gauntlet of two inspections and yet be so bad as to be pronounced unsound directly it is seen by a medical officer of health. We are pleased to notice that the inspection of meat markets was one of the special subjects discussed at the Public Medicine Section of the Belfast meeting of the British Medical Association. Few topics are more deserving of attention.

MISS FLORENCE NIGHTINGALE ON THE CHOLERA.

In a letter appearing in the *New York Herald* Miss Florence Nightingale gives the following practical advice concerning the cholera:—That our whole experience in India, where cholera is never wholly absent, tends to prove—nay, actually does prove—

that cholera is not communicable from person to person. That the disease cannot be ascribed to ‘somebody else’; that is, that the sick do not manufacture a ‘special poison’ which causes the disease. That cholera is a local disease—an epidemic affecting localities, and there depending upon pollution of earth, air, and water and buildings. That the isolation of the sick cannot stop the disease, nor quarantine, nor cordons, nor the like. These, indeed, may tend fatally to aggravate the disease, directly and indirectly, by turning away our attention from the only measures which can stop it. That the only preventive is to put the earth, air, and water and buildings into a healthy state by scavenging, lime-washing, and every kind of sanitary work, and, if cholera does come, to move the people from the places where the disease has broken out and then to cleanse. Persons about cholera patients do not ‘catch’ the disease from the sick any more than cases of poisoning ‘infect’ others. If a number of persons have been poisoned, say by arsenic put by mistake into food, it is because they have each swallowed the arsenic. It is not because they have taken ‘it,’ the ‘mysterious influence,’ of one another.

In looking sadly at Egypt—Egypt, where cholera did not begin anywhere along the route from India to Europe, but at Damietta, where no ship and no passenger ever stops, and where the dreadful insanitary condition of the place fully accounts for any outbreak of cholera—in sorrowfully looking at Egypt and at Europe now, one might almost say that it is this doctrine of a special poison emanating from the sick and which it is thought can be carried in a package that has (mentally) ‘poisoned’ us. People will soon believe that you can take cholera by taking a railway ticket. They speak as if the only reason against enforcing quarantine were, not that it is an impossibility and an absurdity to stop disease in this way, but that it is impossible to enforce quarantine. ‘If only we could,’ they say, ‘all would be well.’ Vigorously enforce sanitary measures, but with judgment—e.g. scavenge, scavenge, scavenge; wash, cleanse, and limewash; remove all putrid human refuse from privies and cesspits, and cesspools and dustbins; look to stables and cowsheds and pigsties; look to common lodging-houses and crowded places, dirty houses and yards. ‘Set your house in order’ in all ways sanitary and hygienic according to the conditions of the place, and ‘all will be well.’ The real danger to be feared is in blaming somebody else and not our own selves for such an epidemic visitation. As a matter of fact, if the disease attacks ourselves we ourselves are already liable to it. To trust for protection to stopping intercourse would be just as rational as to try to sweep back an incoming flood instead of getting out of its way.

MR. CHARLES WINGATE, of New York, points out in the *Medico-Legal Journal*, published in that city, that sanitary legislation in England dates from a very early period. For instance, Edward II. decreed that a butcher who sold diseased pork should be fined for the first offence, pilloried for the second, imprisoned and fined for the third, and expelled the town for the fourth. Richard II. took measures against the pollution of rivers. Henry VII. prohibited cattle-slaying within walled towns with three exceptions. Elizabeth enacted that only one family might dwell in a cottage. The plague, in the time of Charles II., led to many health enactments. More than two centuries ago we read that Shakespeare's father was repeatedly fined by the authorities of Stratford-on-Avon for throwing garbage into the streets in front of his cottage.

THE PUBLIC HEALTH

DURING JULY 1884.

The mean temperature during the month of July at the Royal Observatory, Greenwich, was $63^{\circ}4$; it exceeded by $0^{\circ}8$ the average July temperature in one hundred years, and was as much as $3^{\circ}6$ above that recorded in the corresponding month of 1883. An excess of temperature prevailed on fifteen days of the month, while on the other sixteen days it was below the average. The warmest day of the month was the 4th, when the mean was $72^{\circ}4$, and showed an excess of no less than $11^{\circ}0$; the coolest day was the 26th, when the mean was only $54^{\circ}2$, and $8^{\circ}5$ below the average. Rain was measured at Greenwich on sixteen days during the month, to the aggregate amount of 8 inches, which was $0^{\circ}8$ of an inch below the average July rainfall in sixty-one years. During the first seven months of this year the rainfall amounted to $10^{\circ}7$ inches, which was nearly three inches below the average rainfall in the same period of sixty-one years. The sun was above the horizon during $496^{\circ}8$ hours in July, but only $126^{\circ}5$ hours of bright sunshine were recorded at Greenwich; the amount was considerably below that registered in the corresponding period of any year since 1879. Southerly winds prevailed almost throughout the month.

In the twenty-eight large English towns dealt with by the Registrar-General in his Weekly Returns, which have an estimated population of nearly eight millions and three-quarters, 28,589 births and 19,121 deaths were registered during the five weeks ending the 4th inst. The birth-rate, which had been $35^{\circ}5$ and 46 in the two preceding months, further declined to 40 during July, and almost corresponded with the rates recorded in the same month of the two preceding years, 1882-83. In these twenty-eight towns the lowest birth-rates last month were $28^{\circ}1$ in Bradford, $28^{\circ}2$ in Brighton, and $29^{\circ}2$ in Huddersfield and in Halifax; in the other towns the rates ranged upwards to $40^{\circ}8$ in Nottingham, $41^{\circ}1$ in Cardiff, and $42^{\circ}4$ in Sunderland. The birth-rate last month in London was $32^{\circ}9$, while it averaged $35^{\circ}1$ in the twenty-seven provincial towns.

The annual death-rate in the twenty-eight towns, which in the two preceding months had been $20^{\circ}7$ and $19^{\circ}3$, rose to $22^{\circ}8$ during July, principally owing to the greatly increased fatality of diarrhoeal diseases. This rate considerably exceeded those recorded in the corresponding months of 1882 and 1883, which were $19^{\circ}1$ and $20^{\circ}7$ per 1,000 respectively. The lowest rate of mortality last month in these towns was $14^{\circ}5$ in Bristol. The rates in the other towns, ranged in order from the lowest, were as follows:—Brighton, $14^{\circ}6$; Portsmouth, $15^{\circ}8$; Huddersfield, $17^{\circ}5$; Derby, $18^{\circ}1$; Plymouth, $18^{\circ}2$; Hull, $18^{\circ}4$; Birkenhead, $18^{\circ}6$; Birmingham, $19^{\circ}1$; Bradford, $19^{\circ}3$; Oldham, $20^{\circ}5$; Blackburn, $20^{\circ}8$; Wolverhampton, $20^{\circ}9$; Salford, $21^{\circ}4$; Norwich, $21^{\circ}4$; Halifax, $21^{\circ}6$; Sunderland, $22^{\circ}4$; Bolton, $22^{\circ}7$; Cardiff, $23^{\circ}1$; London, $23^{\circ}7$; Newcastle-upon-Tyne, $23^{\circ}9$; Sheffield, $24^{\circ}0$; Leeds, $24^{\circ}5$; Manchester, $25^{\circ}0$; Nottingham, $25^{\circ}6$; Liverpool, $26^{\circ}7$; Preston, $26^{\circ}8$; and the highest rate during the month, $27^{\circ}3$ in Leicester. While the death-rate in London during July, as above stated, was as much as $23^{\circ}7$ per 1,000, it did not average more than $22^{\circ}0$ in the twenty-seven provincial towns. The 19,121 deaths from all causes in the twenty-eight towns during the five weeks of July included 4,986 which were referred to the principal zymotic diseases, of which 3,012 resulted from diarrhoeal diseases, 540 from measles, 529 from whooping-cough, 66 from scarlet fever, 214 from 'fever' (principally enteric), 132 from small-pox, and 123 from diphtheria. These 4,986 deaths were equal to 26 per cent. of the total deaths, and to an annual rate of $5^{\circ}94$ per 1,000. This zymotic rate, owing to the prevalence of summer diarrhoea, considerably exceeded that recorded in recent months, and also was above the rate from the same diseases in the corresponding months of either of the two preceding years. The zymotic death-rate in London during July was

as much as $7^{\circ}03$ per 1,000 (of which $4^{\circ}52$ was due to diarrhoea), whereas it did not exceed $5^{\circ}01$ in the provincial towns, among which the diarrhoea rate was $2^{\circ}95$ per 1,000. The zymotic rates in the provincial towns ranged from $1^{\circ}1$ and $1^{\circ}8$ in Huddersfield and Bristol, to $7^{\circ}5$ in Liverpool, $7^{\circ}8$ in Nottingham, $9^{\circ}0$ in Preston, and $10^{\circ}4$ in Leicester.

Diarrhoea was by far the most fatal zymotic disease in the twenty-eight towns during July. The rate of mortality from this disease in these towns, which had been but $0^{\circ}37$ in June, rose to $3^{\circ}67$ during July, and exceeded that recorded in the corresponding month of 1883, when it did not exceed $2^{\circ}40$ per 1,000. The diarrhoea death-rate last month did not exceed $0^{\circ}49$ in Huddersfield, $1^{\circ}07$ in Wolverhampton, and $1^{\circ}09$ in Halifax; while it ranged upwards in the other towns to $4^{\circ}53$ in Leeds, $6^{\circ}00$ in Nottingham, $7^{\circ}34$ in Preston, and $8^{\circ}80$ in Leicester. While the rate of mortality from diarrhoea was $4^{\circ}52$ in London, it did not average more than $2^{\circ}95$ in the twenty-seven provincial towns. The death-rate from measles, which had been $0^{\circ}94$ and $0^{\circ}92$ per 1,000 in the two preceding months, further declined during July to $0^{\circ}64$. In London the rate from this disease was $0^{\circ}60$, and the highest rates among the provincial towns were $1^{\circ}98$ in Liverpool, and $2^{\circ}08$ in Blackburn. The rate of mortality from whooping-cough was $0^{\circ}63$ per 1,000, and showed a further decline from the rates in recent months, although it considerably exceeded the rate recorded in the corresponding period of last year. In London the rate from this disease was $0^{\circ}73$ per 1,000, and among the provincial towns the highest whooping-cough rates were $1^{\circ}02$ in Leicester, $1^{\circ}11$ in Liverpool, and $2^{\circ}37$ in Sunderland. The death-rate from scarlet fever, which in the eight preceding months had steadily declined from $0^{\circ}84$ to $0^{\circ}35$ per 1,000, rose again during July to $0^{\circ}44$. In London the rate of mortality from scarlet fever was equal to $0^{\circ}38$ per 1,000, while in the twenty-seven provincial towns it averaged $0^{\circ}48$, and showed the highest proportional fatality in Wolverhampton, Sheffield, and Cardiff. The death-rate from 'fever' (principally enteric or typhoid) showed a slight increase upon recent monthly rates, and was considerably higher in London than in the aggregate of the provincial towns. The rate of mortality from diphtheria corresponded with the rate in the preceding month; this disease showed some prevalence in London, but very few fatal cases were recorded in the provincial towns. During the five weeks of July 132 fatal cases of small-pox were registered in the twenty-eight towns, showing a marked decline from the number during June; of these, 102 were returned in London, 13 in Liverpool, 6 in Sheffield, 5 in Hull, 5 in Sunderland, and 1 in Cardiff. Judged by the returns of the Metropolitan Asylum Hospitals, the prevalence of small-pox in London showed a further considerable decline throughout July. The number of small-pox patients under treatment in these hospitals, which in the nine previous months had steadily increased from 41 to 1,290, declined to 892 at the end of July. The average weekly number of new patients admitted to these hospitals, which had risen from 18 to 275 in the six previous months, fell during July to 151.

The rate of infant mortality in the twenty-eight towns, measured by the proportion of deaths under one year of age to births registered, was equal to 246 per 1,000 during July, against 163 and 195 in the corresponding periods of the two preceding years, 1882-83. This increase was entirely due to the excessive fatality of summer diarrhoea, which caused very high rates of infant mortality in many of the towns. While the infant mortality did not exceed 131 per 1,000 in Brighton and Bristol, where but little diarrhoea existed, it was equal to 303 in Nottingham, 326 in Preston, and 453 in Leicester, where the highest death-rates from diarrhoea were recorded.

The death-rate from diseases of the respiratory organs, judged by the metropolitan returns, differed but slightly from the average during July. The weekly number of deaths referred to these diseases in London averaged

1894, and the annual death-rate was equal to 3.52 per 1,000. In Liverpool the annual rate of mortality from these diseases was last month equal to 3.80 per 1,000.

The causes of 390 of the 19,121 deaths registered in the twenty-eight towns during the five weeks of July were not certified, either by medical practitioners or by coroners. These uncertified deaths were equal to 2.04 per cent. of the total deaths, which was below the average in recent months. In London the proportion of uncertified deaths did not exceed 1.07 per cent., while it averaged 2.92 in the twenty-seven provincial towns; and ranged from 0.00 and 0.76 in Portsmouth and Plymouth, to 5.00 in Hull, 5.81 in Oldham, and 7.41 in Birkenhead.

Among the population living in the outer ring of suburban districts around London, estimated at rather more than a million persons, the annual death-rate during July from all causes was equal to 18.9 per 1,000, against 14.6 and 16.7 in the corresponding periods of 1882 and 1883. During the five weeks ending the 2nd instant, 313 fatal cases of diarrhoea, 69 of whooping-cough, 29 of measles, 24 of small-pox, 23 of diphtheria, 19 of 'fever,' and 12 of scarlet fever were recorded in the outer ring. These 488 deaths were equal to an annual rate of 4.74 per 1,000, which considerably exceeded the rate recorded in the same month of the two previous years. The fatality of measles and scarlet fever showed a decline, but that of each of the other zymotic diseases showed an increase. The 24 deaths from small-pox registered in the outer ring included 15 in West Ham, 3 in Croydon, and 2 in Hornsey. Six fatal cases of diphtheria occurred in Tottenham sub-district, and 6 of measles in the sub-district of Bromley.

THE use of tube or Abyssinian wells for obtaining water in rural districts has often been resorted to, and almost invariably with success. This plan, which possesses many obvious advantages over the ordinary open well, has been tried with excellent results at Watford. In referring to the subject in a recent report, Dr. Saunders suggests that the sanitary authority should obtain the necessary tackle and lend it to persons whose means are small. At this time of the year, when the usual supplies of water in many districts are getting scanty, the suggestion is well worthy of a trial.

M. HYADES has written a memoir on the hygiene of the Fuegians which he studied during his visit to Terra del Fuego. His memoir contains also considerable information on affections peculiar to the Fuegians. It might have been reasonably expected that the hygiene of the Fuegians would have been open to the celebrated description by the schoolboy of the habits and manners of the Romans!

THE Sanitary Authorities of St. Pancras have resorted to a special organisation of their staff to make a house-to-house call weekly, not only for the purpose of looking after the water-supply and drainage, but to see that the dustbins are clear of animal and vegetable refuse. A number of men are employed in following the carts, supplied with carbolic acid, and as soon as the bins are cleared commence their work of disinfecting. It is a most remarkable fact that four-fifths of the inhabitants exhibit annoyance at the weekly visits, and in the majority of cases will not allow the dustbins to be emptied until they are overflowing with refuse. This circumstance, however, only puts in a stronger light the urgent necessity, especially during hot weather, of removing all the multifarious decomposing matter of which the so-called dustbin is the receptacle in all neighbourhoods, rich as well as poor. The Vestry of St. Pancras have shown practical common sense in the step which they have taken, which should be imitated by every parish. Very forcible and stringent measures are required to prevent many of the inhabitants of this vast metropolis from becoming piggishly indifferent to dirt and bad smells.

NOTIFICATION OF INFECTIOUS DISEASE.

THE question of the compulsory notification of infectious disease, and especially of the person by whom such notification is to be made, appears to have now taken firm root as one of the most pressing sanitary problems of the day. It was hardly to be expected, perhaps, that there should be absolute unanimity with regard to it on the part of the medical profession; but one was scarcely prepared for the complete opposition of opinion which has been revealed by recent discussions at the International Health Exhibition and elsewhere. We publish to-day two admirable papers on the subject by two acknowledged leaders of the sanitary world. The one argues strongly in favour of notification by the medical man; the other argues just as strongly in opposition to it. The one treats as of no importance objections which seem to the other to be of paramount weight. If we could print the opinions of these two authorities in parallel columns, such of our readers as do not possess an abnormal development of the critical faculty might well stand aghast, and wonder how with views so divergent as these, there could be any hope of the system of compulsory notification making progress at all. The answer is to be found in the words of Goethe: 'More light'; and it is with the view of shedding more refulgence upon the question that we inaugurate the system of returns to which we refer more at length below. After all, a system of whatever kind must be judged by its results; and the outward and visible sign of those results is, in the case before us, a diminution of the prevalence of fatality of zymotic disease. We have before pointed to the futility of merely collecting together for dry statistical purposes a record of the zymotic sickness in this or that district. The notification return, though useful of course for reference and table-making, should be regarded primarily as a danger signal, upon which the local authorities, if they are wise, will lose no time in acting.

There are reasons for belief that before very long a general inquiry into notification and its results, actual and proposed, will be undertaken by the Government. Such an inquiry has been recommended by the Special Committee which was appointed this session to deal with the various Corporation Bills containing sanitary clauses, and it is apparently coming to be generally recognised that the present haphazard method of dealing with the matter can be endured no longer. Meanwhile, we think it useful and instructive to place upon record each month the numerical results of disease-notification, as obligingly furnished to us by the various medical officers of health. Later on it may be possible, from a study of the returns and of the Registrar General's figures about towns not included in the tables, to form some sort of statistical judgment as to the propriety of extending the system of compulsory notification throughout the country. At present the materials for such a judgment do not exist; and it is especially with the object of helping towards a calm and impartial consideration of the question that our returns of infectious sickness have been organised.

The following table contains uniform statistics for sickness and mortality in twenty-eight of the thirty-eight urban sanitary districts in England and Scotland in which the notification of infectious disease is compulsory. We hasten to take this opportunity gratefully to acknowledge the very general response of the medical officers of health whose co-operation we invited in this matter. We are pleased to be able to state that the health officers of a very large majority of the thirty-eight towns in which notification is compulsory have most readily responded to our appeal, and we are glad to be enabled to publish our first monthly table so nearly complete. We have every reason to hope that the number of contributors will increase. We would specially thank the medical officers of health for the prompt dispatch of their cards. While we are fully aware of the difficulty which is often experienced in furnishing the required information immediately after the close of the

month, we venture to hope that, whenever practicable, the cards may be posted during the first four days of the month, as the table is prepared under pressure, which can be greatly lessened by the early transmission of the cards. In one respect, and one only, the uniformity of our statistics is not quite so complete as we could wish it to be. A large proportion of the facts are no doubt compiled from weekly returns. In these cases the monthly return will sometimes embrace four, and occasionally five, weekly returns. In order to secure uniformity, it may be useful to remember that a week should invariably be included in that month to which the greater number of its days belong. For instance, if the monthly totals are made up from weekly returns, those for the month of July now under review should consist of five weeks ending the 2nd instant; and the return for our next issue should relate to the four weeks ending August 30. Returns for calendar months are, however, much preferable whenever it is possible to obtain them.

The estimated population of the twenty-eight towns, for which we are enabled to publish complete statistics for the month of July last in the accompanying table, is nearly two and a half millions. The annual death-rate from all causes during that period in these twenty-eight towns averaged 19·53 per 1,000 persons estimated to be living therein. The death-rates were considerably below the average in Barrow-in-Furness, Burton-upon-Trent, and Reading; while they showed an excess in Halifax, Jarrow, Bolton, Warrington, Preston, Nottingham, and Leicester. Most of these higher rates of mortality were in great measure due to the excessive prevalence of diarrhoeal diseases. The death-rate from the eight infectious diseases dealt with in the table, concerning which notification is compulsory, averaged 0·57 per 1,000 in the twenty-eight towns furnishing this information. No death from any of these diseases occurred in Burton-upon-Trent; in the other towns the rates ranged from 0·15 in Derby, 0·16 in Dundee, and 0·25 in Bradford, to 1·07 in Preston, 1·14 in Lancaster, and 1·74 in Burnley. Turning to the notified cases of infectious disease in these twenty-eight towns, we find that the average proportion to the population of persons reported to be suffering from one or other of the eight diseases enumerated in the table was 3·86 per 1,000. No death was notified from any of these diseases in Rotherham during last month; in the other towns the proportions of notified cases ranged from 0·55 in Macclesfield, 1·39 in Accrington, and 1·90 in Burton-upon-Trent, to 5·28 in Bolton, 5·53 in Burnley, 5·81 in Derby, and 10·06 in Salford. Turning to the several diseases, we find that scarlet fever showed the greatest proportional prevalence in Bolton, Burnley, Derby, and Salford; enteric fever in Preston, Edinburgh, Jarrow, and Barrow-in-Furness; typhus in Aberdeen and Birkenhead; and diphtheria in Salford and Nottingham. Cases of small-pox were only notified in four of the twenty-eight towns—Aberdeen, Birkenhead, Bolton, and Salford. The total deaths in these twenty-eight towns from the eight diseases were 128, and the notified cases 862; it would appear, therefore, that, if all the cases were properly notified, the mortality must have been nearly 15 per cent. of those attacked. The mortality among the scarlet fever cases, according to the totals, appears to have been equal to nearly 15 per cent., and among enteric fever cases to as much as 27 per cent. The general mortality from scarlet fever and enteric fever, judged by hospital statistics, may be said to be about 10 and 20 per cent., respectively, of persons attacked. The percentages in the twenty-eight towns last month show, therefore, a considerable excess, and are probably overstated from a certain proportion of the cases escaping notification, while every death is necessarily reported.

It was stated at the last monthly meeting of the Blaydon Local Board that much mortality was occasioned at Black-hill Mill through deficiency of the quantity and quality of the water supply.

SPECIAL REPORTS.

THE PARKES MUSEUM.

At the annual meeting held on July 9 (Captain Galton in the chair) a letter was read from the Westminster regretting his inability to attend the and a report was read by the chairman of it showing the valuable work that had been carried on at the museum during the past year. Twenty-one have been arranged by the Council, and the museum by some of the best authorities on and sanitary science. These lectures have much valuable information, and have dealt with of the subjects included in the scope of the in a most useful and interesting manner. The has been largely used by lecturers on public and other skilled teachers for practical demonstration to various classes of students, &c., who for this have been admitted to the museum without ent. In this way the special advantages offered by the museum have been utilised for the purpose of a large number of students and others, who by of their several callings may be expected in the future to exercise an important influence in the promotion of health in connection with the construction of and otherwise; and the Council are glad to see the facilities thus offered have been fully appreciated by teachers and students having expressed a desire for further opportunities of the same sort might be afforded. The members numbered 99 on June 30, 1883, just opening of the museum; they now number 260. In the year the museum has been visited by 6,870. The lamented president, His Royal Highness Leopold, Duke of Albany, in his inaugural address on May 26, 1883, said that the sole object of the museum 'to disseminate and to help others in disseminating laws of health.' The sphere of work thus foreseen by the late Duke of Albany has (as will be seen in those who peruse this report) become an accomplished fact in every particular. The utility of the museum has increased month by month. The museum has met a great public want; and the Council would strongly urge upon the members and upon all interested in sanitation to use their personal influence so to increase the number of members and life of the museum that the future of so valuable an institution may not be a matter of doubt.

THE NATIONAL SMOKE ABATEMENT INSTITUTION.

A WELL-ATTENDED meeting, convened by the Council of the National Smoke Abatement Institution, for consideration of the Bill now before the House of Commons to amend the Smoke Abatement Acts, and for business connected with the institution, was held on July 16 at the Mansion House. The Lord Mayor presided for a short time, and was succeeded by Mr. Mount-Temple.

The annual report, which was read by Mr. Hart, stated that the past year was really the best which the movement had worked in an organized and had had the opportunity of indicating and demonstrating its practical utility. In most of the large towns, as in numerous smaller places where the public had been freely circulated, the necessity of abating smoke had been generally recognised, and the subject was now one of active public discussion. Opinion had been expressed with marked emphasis in favour of the year, and the attention of sanitary boards had been called to the injurious effects of smoke on health. At the last annual meeting some of the large bakeries had adopted the improved gas-heated and other

were now worked without any smoke whatever, turning out large quantities of bread prepared under more cleanly and healthy conditions. A number of gas engines now used in London was at 6,000, and the uses of smokeless coals and of heating purposes had also largely increased. And though a Royal Commission should be appointed to inquire into the means of preventing smoke, application had been made to the Government, and that they were not disposed to grant one. It was introduced by Lord Stratheden and Campbell provisions for the supervision and control of the arrangements of all new buildings, including houses, in order that smoke from them might be prevented. It further provided for local authorities empowered to create, subject to the approval of the secretary, by laws for the restraint of smoke in certain districts, as well as to extend the provisions of the Smoke Abatement (Metropolitan) Acts to the metropolitan police districts, and to include chimneys and furnaces which were not at present included. (See SANITARY RECORD for June 15, p. 591.) The result from smoke and fog was so great as to have led to great epidemics. There had only been one in London that had caused more deaths than had been traced to fog and smoke. The resolution was introduced by Lord Stratheden and Campbell, who expressed his hope of being able to carry his Bill through the House of Lords.

Mr. Pollock next moved: 'That this council has with satisfaction, the introduction into the House of Commons of the Smoke Nuisance Abatement Bill by Lord Stratheden and Campbell, and that it trusts that this Bill will receive favourable consideration from Parliament with the view to the adoption of such means as may be necessary to abate the evils arising from the excessive production of smoke within the metropolis.' This was seconded by Mr. George Shaw, chairman of the City Sanitary Board, who said he believed if the Bill proceeded on the lines they had already entered upon it would meet with great success. The resolution was carried *unanimously*, and the proceedings closed with the singing of votes of thanks to the Lord Mayor and the Lord Bishop of London.

VACCINATION OFFICERS' ASSOCIATION.

A monthly meeting of this association was held at the Cross Hospital Medical School on Saturday, June 15. Mr. C. Shattock in the chair, Dr. Henry Stevens, President of the Local Government Board, being present. The members proceeded to consider Dr. Cameron's report made in the House of Commons upon July 1, 1883, to the system of vaccination practised in the metropolis compared to that pursued in Glasgow during times of epidemic, and resolved to request each member of the association to furnish the secretary with the following information:—1. To show how promptly on the action of the vaccination officer the protection of vaccination can be given to those in infected houses. 2. Any instances in which prompt action has illustrated its advantages. Mr. O. Elkerton (honorary secretary), in calling attention to the pamphlet issued by the National Health Society upon the subject of vaccination, proposed the following resolution:—

Resolved, that the members of the Vaccination Officers' Association hereby express our most cordial thanks to the National Health Society for the pamphlet issued by them, which calls the attention of the public to facts concerning vaccination; and would further desire to mark their appreciation of the thoughtful kindness which prompted the National Health Society to assist the vaccination officers of the metropolis in the discharge of their difficult

distributed, and most beneficial results had accrued from their so doing—as the attention of the public was thereby not only called to the protection afforded by vaccination, but it also convinced them that the Vaccination Acts were for their benefit. That the truth about vaccination should be known to the public was most important; and when 'Facts concerning Vaccination' were placed before those capable of receiving evidence, there could be no doubt about the good this pamphlet would do. There are always a certain number of people who obstinately refuse to be convinced either by arguments or results, with whom—as members of this association were well aware—it required more than ordinary patience to deal. Experience proved that opponents do not draw the line of opposition at vaccination. Objection here and there must be expected by officers; hence the necessity of the law. It would be difficult to name any Act of Parliament universally accepted as an unqualified blessing. When one knows that some people object to soap and water, and others to policemen, it cannot be matter of surprise that some object to vaccination. It is a matter of history that there are people so peculiarly constituted that everything is objectionable to them but the sound of their own voice, raised in execration against everybody and everything; and it would be well for all if such people could be inoculated with an idiosyncrasy against their own voice. In the early days of our association a strong wish was expressed that we should become rich enough to publish for public information statistical evidence bearing upon the benefits of vaccination. That we have been anticipated so kindly by the National Health Society is a matter of congratulation for them and for us. The literature issued by anti-vaccinationists has been permitted to permeate and poison the public mind for a long period uncontradicted, and the abusive language employed by anti-vaccinationists against the issue of this pamphlet is the strongest possible proof that the National Health Society can have of the great good it has done. It is the old tale, 'No case—bully the plaintiff's solicitor.' It is sincerely to be wished that this pamphlet will act only as a pioneer to a series of such publications.

Vaccination officers cannot call individually upon every client, bringing under their notice evidence of the protective power of vaccination; and this pamphlet will go a long way to help officers in their duty, and prove an antidote to antagonistic perversions of facts. It would be a source of further assistance to officers if the higher authorities would place in their hands official records of statistics, which in some instances they help to compile. Being supposed to be always ready with arguments founded upon statistical evidence, it is not too much to expect that the means should be ready to their hands. Opponents have been very busy in the distribution of their publications, and the result, as recently reported, ends in a 'conscientious objection,' sympathetically condoned by the fine of half-a-crown. Some day, perhaps, the vaccination officer will be allowed the benefit of legal assistance to conduct a prosecution, and be placed otherwise than at a disadvantage when his duty compels him to take legal proceedings.

Mr. W. B. Croft seconded the resolution, and, referring to the issue of the pamphlet in Fulham, spoke of the good results obtained. Some Boards of Guardians, while averse to the system of a house-to-house visitation, as an alternative published the pamphlet, and it was considered by many that equally good results had been obtained.

The resolution was then formally put to the meeting and carried unanimously.

THE CRYSTAL PALACE ELECTRIC AND GAS EXHIBITION AWARDS.

On the 6th inst. the Duke of Buckingham and Chandos presented the awards to the exhibitors at the Crystal Palace International Electric and Gas Exhibition of 1883.

The secretary stated that in St. George's Union the association had ordered 21,000 of these pamphlets to be

The ceremony took place on the great Handel orchestra of the Crystal Palace.

The awards distributed were in connection with the gas section of the exhibition, and the following is the list of the awards:—Gold medal for the Grimston regenerative gas burner (exhibited by G. Bower); gold medal for F. W. Clark's regenerative gas burner (exhibited by the Portable Gas Apparatus Company); silver medal for Sir James N. Douglass's burner (exhibited by the Improved Gas and Oil Burners Company, Limited); silver medal, William Sugg & Co., Limited, for gas burners. For Flat-flame Burners with governors: Another silver medal to William Sugg & Co., Limited; and for Flat-flame Burners in lanterns, a further silver medal to William Sugg & Co., Limited. For Incandescent Burners: Silver medal for the Clamond burner (exhibited by E. Servier); silver medal for the Lewis burner (exhibited by G. Bower); and silver medal, Albo-Carbon Light Company, Limited, for their method of increasing the illuminating power of gas. For Cooking Stoves: Silver medal, H. C. Davis & Co.; silver medal, J. Wright & Co.; silver medal, General Gas Heating and Lighting Company, Limited; silver medal, Waddell & Main; and silver medal, Strode & Co., for their summer and winter stove. For Close Heating Stoves: Silver medal, John Wright & Co.; silver medal, General Gas Heating and Lighting Company, Limited; and silver medal, William Sugg & Co., Limited. For Asbestos Fuel Stoves: Silver medal, West Brothers. Tile Stoves: Silver medal, General Gas Heating and Lighting Company, Limited; and Reflector Stoves: Silver medal, Strode & Co. For Instantaneous Water Heaters: Silver medal, William Sugg & Co., for Therma Heater; and silver medal, Strode & Co. For Gas Governors: Silver medal, James Stott & Co. The general awards were: Diploma of honour, George Glover & Co., for the general excellence of their exhibits; diploma of honour, W. Parkinson & Co., for the general excellence of their exhibits; silver medal, Pintsch's Patent Lighting Company, Limited, for their gas apparatus; silver medal, Thompson's Smokeless Kiln and Oven Company, Limited, for their kiln; silver medal, The Portable Gas Apparatus Company (F. W. Clark), for their apparatus for manufacture of gas; and silver medal for Fletcher's apparatus for the application of gas to heating purposes (exhibited by Deane & Co.).

BAD SMELLS.—Numerous complaints from all parts of London, including the House of Commons, have lately been made respecting more offensive smells in almost all parts of London. As regards those noticed at the Houses of Parliament it is stated that they arise partly from the sewers and partly from manufactories. The same is said of those which are referred to in Old Ford, Bow, and Hackney, with the addition of most fetid smells from the Lea and its outfall into the Thames. There is no doubt as to the correctness of the complaints, but they are chiefly evolved from manufactories, and carried to a considerable distance before they descend to ground level. Thus, although there are very few offensive businesses carried on in Hackney, yet most objectionable smells are said to pervade the parish either from the Haggerstone Gas Works, or from manufactories at Bow, Poplar, and Stratford. As usual, these works are under the divided control of three authorities—viz., the Metropolitan Board of Works, and Local Sanitary Authorities in the metropolis, chiefly the former, and the Local Government Board outside London. Now as the three parishes just named are adjacent to Stratford, which is outside the metropolis, the Local Government Board is responsible for the continuance of the smells given off in that place. Under these circumstances, those who suffer do not know to whom their complaints should be addressed. It is quite true that in this, as in other sanitary matters, there should be greater unity of action in the oversight of offensive trades, and more simplicity as well as rapidity in proceedings for the removal of nuisances.

REPORTS OF MEDICAL OFF OF HEALTH.

'Something attempted, something done.'

BELPER RURAL.—Mr. Gaylor prefaces his the Alfreton division of this district with son remarks setting out the leading features of the statistics, and the principal items of sanitary plan which might well be adopted by all health large and straggling rural districts. In some water supply has been improved, but owing to and other difficulties many of the inhabitants continue to use their wells and pumps although mains almost pass their doors. The drains received particular attention from Mr. Gaylor, that no fresh communications between the sewers inside of houses have been permitted. In many an entirely new arrangement has replaced the old, this is costly it cannot be proceeded with yet. Scarlet fever caused some trouble at Alfreton prevailed extensively during the last half of 1888 ten deaths. Altogether zymotic diseases destroyed lives, representing a death-rate of 1.12 per mortality from all causes being equal to 16.6 in In reporting on the other portion of the division Belper division, Mr. Allen discusses at some length fatality from preventable causes, which he sums up in a very able and convenient manner. He does not rehearse to his authority the many lessons which valence of these diseases should inculcate, and he them that their first duty is to provide proper accommodation. At Kirk Langley there was an outbreak of scarlet fever which baffled all efforts to trace but from subsequent investigation in another part of the district, Mr. Allen is of opinion that pedlars are often play an important part in spreading disease. Measles and whooping-cough caused two out of a total of twenty-eight attributed to the zymotic diseases. The general death-rate was 14.0 per 1,000, which would be satisfactory enough if not for the large mortality registered amongst In various villages schemes for the extension of and water supply are in progress, and special attention been directed towards improving the mode of disposal, by abolishing cesspits and erecting earthen and ash-pits in their stead. For the Alfreton division Mr. Gaylor reports a death-rate during 1883 of 16.6 per against an average of 14.69 for the previous eleven years. Thirty-eight per cent. of the total number of deaths occurred amongst children under five, and 30.5 amongst persons aged sixty and upwards. In the division the general rate of mortality was equal to 14.9 per 1,000. More than one-third of the whole of deaths happened at the threshold of life, affording to the subject Mr. Allen animadverts the system of life insurance amongst children. Diseases destroyed twenty-three lives, scarlatina accounting for eleven deaths.

BOURNEMOUTH.—The year 1882 was one of unusual activity in Bournemouth, for during this period commenced an elaborate system for flushing and ventilating the main sewers, which Mr. Nunn describes as one of the best sanitary improvements effected for many years. Boscombe and Springbourne the inhabitants were complying with the notices directing the connection of their house-drains with the extended sewers, and a portion of the town no little improvement will result from the discontinuance of the offensive soak-pits. Progress is being made in this respect, Mr. Nunn draws the serious attention of his authority to the grave danger caused by a large deposit of refuse, which, by offensive putrefaction, disgusts a whole neighbourhood. Obviously this is not right or politic, and steps are being taken for relieving the district of an evil so just

1 of. Estimating the population at 18,000, and the deaths of visitors, the death-rate is as low as per 1,000. Whooping-cough was the most fatal of motics, causing 19 deaths, 8 being referred to a. In referring to the prevalence of infectious, Mr. Nunn laments the absence of a hospital, and that his authority will promote the erection of a g so essential to the welfare of their district, which inaptly described as a national sanatorium. The e of this provision was severely felt during 1883, the ation of scarlet fever into the district being attended erious pecuniary loss both to the patients and the t-house keepers. The lesson, however, has not est upon the authority, who at length have resolved eed with the erection of a hospital. Indeed, at the the report the plans had already been passed, and ann observes that the building, when completed, e one of the most perfect in the kingdom. The of refuse removal still needs improvement, and in ortions of the town overcrowding exists to a dan- extent. The death-rate, after deducting the deaths ors, was as low as 7.36 per 1,000.

SETT. — The dwellings of the poorer classes in this seem to be in a terrible condition. Many of the s have scarcely more than a yard of ground save 1 which they stand, and some are absolutely without The offices in such cases are crowded close to the or built on to the pantry. Bedroom accommodation entably deficient; in very few dwellings are there han two bedrooms provided, and in most of them is only one. It is the exception, Dr. Renton es, to meet with a cottage with fireplaces in its bed- and where the fireplace is absent proper ventilation room is impossible. Having regard to these con- it is not surprising to learn that there was a high f mortality recorded for 1882, in which zymotic : largely figured. There was some prevalence of eria and of enteric fever, mostly in a sporadic form, he exception of two outbreaks of this last disorder were undoubtedly due to a specifically polluted here. An extensive epidemic of measles began in and terminated in the autumn, but of some hundreds e eight only proved fatal. The total number of registered in the district was 166 (of which 83, or 1 one-half were those of children under five), return- leath-rate of 21.7 per 1,000 against 14.8 recorded in

The sanitary condition of the district is very ve. House accommodation is of the worst possible excrement removal is imperfectly carried out, and, consequence, masses of filth abound. Dr. Renton roperly advises his authority to take under its own al control the cleansing, whitewashing, and disin- of the ashpits and privies, if this nuisance, second n order of gravity of the sanitary evils of the district, e overcome. Some progress was made during the n the extension of the main sewers, and in the sub- n of water-closets for offensive privies; but it is is that much more remains to be done. During the sewerage system continued to progress, and there decided improvement in the scavenging of the town, is to be regretted that the authority cannot be pre- upon to undertake the cleansing of ashpits and e. Dr. Renton, who has much of interest to say in l to the dwellings of the poor in his district, returns eral death-rate at 14.3 per 1,000, which, with one tion, is the lowest recorded since the adoption of the Government Act.

'PLACE TO LIVE IN. — The Cleethorpes Medical Officer ealth, in his quarterly report, states that in that t, with a population according to the last census of t, there was no death from March 27 to May 17, only eaths from May 17 to June 7, and five during the der of the quarter. The total death-rate for the as 9.6 per 1,000; deducting premature deaths and sta, 5.2 per 1,000.

SANITARY INSPECTORS' REPORTS.

ASTON MANOR. — Mr. Bolt's report contains a record of much patient and methodical work, which was carried out without the necessity of having recourse to legal proceedings in any single case. An inspection of the bake-houses of the district showed but too clearly that they stood in need of sanitary supervision, no fewer than 22 being found in a filthy condition. The larger portion of the 1,193 notices that were issued were readily complied with. In 244 instances the drains were repaired and cleansed, in 214 wet and dilapidated middens were reconstructed, and in 102 house-drains were disconnected from the sewers. An immense number of visits were paid to the slaughter-houses, &c., and proper observation was exercised over nuisances caused by the emission of smoke. A house-to-house inspection of one portion of the district revealed the existence of numerous sanitary defects, which were promptly remedied. During the year the inspector collected 180 samples under the provisions of the Food and Drugs Act 1875, and submitted them to the public analyst, with the result that 17 vendors were proceeded against and fines amounting to 42*l.* were inflicted.

BROMINSTER RURAL. — Mr. Marsh's report would deserve notice if only for the fact that it has been prepared without having recourse to statistical statements. There are, however, signs of much good work of an unpretending character having been performed during the year. Particular attention was directed towards maintaining the existing drains in a proper condition, in supervising the construction of new sewers, and in examining all house connections. The water supply of the district was considerably improved by the extension of the public water mains to Easton-in-Gordano, the inhabitants of which had hitherto been dependent upon the water running in the road. The inspector does not record the number of nuisances disposed of, but he shows that some cases of overcrowding were abated, and that disinfection was energetically carried out during the prevalence of scarlatina.

BELPER RURAL. — Considerable extension was made in the water service of this district during 1882, no fewer than 973 houses, with 4,643 occupants, having been supplied. To secure this Mr. Clexton issued 472 formal notices upon owners and agents, all of which were complied with, and later on 313 official orders. These, however, did not receive such prompt recognition, since at the close of the year 76 were outstanding. At Waingrove a number of wells were protected on the representation of the inspector, who submitted 117 samples of water for analysis. In reference to works of drainage, Mr. Clexton's report is not so complete as could be wished, as he gives no details of his labours in this direction beyond stating that a considerable portion of his time was occupied in superintending the making and connection of drains. A number of houses, water- and dry-earth closets, receptacles, &c., were erected, and plans for similar structures were submitted for examination previous to the works being commenced. The inspector states that he notified 552 nuisances, a large proportion of which were abated, but no information as to their nature appears in the report. Mr. Clexton's report for 1883 is written in the same lines as its predecessor. Thus, amongst other items, he states that he inspected 2,046 dwelling-houses and reported 998 nuisances, which, however, are not specified. This is an obvious defect, and one that should be remedied in future. The inspector seems to have been active in his district, and there are signs of the performance of good work, though Mr. Clexton does not make this so clear as could be wished.

CHESTER-LE-STREET RURAL. — In his tenth annual report Mr. Barras gives a succinct account of the sanitary work performed by him during 1883. Reference is again drawn to the increasing number of nuisances that arise from offensive accumulations, and to the fact that the

Authority can satisfactorily dispose of them by contracting for the regular removal of refuse, under section 42 of the Public Health Act. Having regard to the danger arising from the retention of the contents of privies and ashpits, and to the success that has invariably followed the adoption of this section elsewhere, it is to be regretted that the Chester-le-Street Authority have not thought fit to follow the advice of their inspector. The year witnessed the performance of some useful sanitary work, though in the south-west portion of the district there is an obvious need for an extended water supply, which unfortunately the Water Company cannot so far be prevailed upon to provide. With a view to securing a more prompt response to the notices issued for the abatement of nuisances, &c., Mr. Barras suggests that he should be empowered to take legal proceedings as soon as the order expires.

COVENTRY URBAN.—Like its predecessor, Mr. Booker's report is excellently arranged, no point of importance being overlooked. Much work seems to have been done towards maintaining the district in a sanitary state and free from nuisance. Ninety water-closets were provided with proper flushing arrangements, 50 houses were supplied with town water, 105 sink drains were disconnected, and 115 filthy and unwholesome dwellings were cleansed and lime-washed. Fifteen privies were abolished, 17 were repaired, and 50 were converted into water-closets. In eight instances overcrowding was abated, while ten houses were closed as unfit for habitation. Altogether, 712 improvements of more or less importance were effected, as compared with 610 in the previous year. Two proceedings were taken against the retailers of meat unfit for food, one of whom was mulcted in a substantial penalty, and six butchers were summoned for neglecting the by-laws relating to slaughter-houses. In other respects much useful work was performed.

DONCASTER RURAL.—Very considerable progress was made in this district last year. The whole of Balby was lighted with gas, the streets named, the houses numbered, and the drainage arrangements almost completed. At Bentley a new sewer was laid in place of an open offensive ditch, at Braithwell a public well was protected from pollution, and at Ardwick additional sewers were laid. In other parts of the district special attention was directed to the cleansing of wells and brooks, and to the flushing and ventilation of the sewers. Out of 164 notices issued by Mr. A. Wright, the surveyor and sanitary inspector, 20 related to water, 71 to drainage sink-pipes, 15 to privies and ashbins, and 30 to pig nuisances. The report does not show, however, how many of these notices were complied with.

EAST DEREHAM.—The first portion of Mr. Nankivell's report is occupied in an attempt to refute the belief held in some quarters that the prosperity of the town is declining, and in so doing he gives some useful statistics of the sanitary work that has been performed since the completion of the schemes of water and sewerage. He reports that there are now supplied with water from the Public Works, and connected with the sewers, some 146 water-closets, of which 53 belong to cottage property and 93 to private houses. The addition of a properly equipped closet to cottages is no inconsiderable improvement, the more so when it is remembered that the majority of these dwellings under the old system were scarcely fit for habitation from the proximity of defective and ill-constructed middens. Mr. Nankivell properly exercises much supervision over the connection of house drains with the public sewers, and he has been well advised in adhering to the principles set out in the model by-laws of the Local Government Board. The sewage farm continues to work well, the value of the crop of osiers being estimated at over 20*l*.

GOOLE RURAL.—The report of Mr. Tudor, C.E., the surveyor and inspector of this district, is statistical only; but it contains a record of the performance of much useful work. During 1883 as many as 1,140 yards of

new main drainage were laid in various portions of the town, 8,190 yards of foul stagnant village watercourse were cleansed, 104 house-drains were examined and reconstructed, 56 old brick cesspools were removed, and 29 houses connected with the new sewers. Mr. Tudor made 550 inspections, and abated 300 nuisances. A considerable number of ashpits and privies were reconstructed, 27 premises were disinfected after the prevalence of infectious disease, and the lodging-houses were inspected, cleansed, and limewashed.

GOOLE URBAN.—Mr. J. F. Hedley reports that during 1883 he made 1,240 inspections, reported 176 nuisances and abated 142. Ten common lodging-houses were registered, 33 premises were disinfected, 42 ashpits were either repaired or covered and ventilated, 32 cesspools were replaced with pot gullies, and 50 box-closets were renewed; 334 yards of new sanitary pipe-drains were laid to houses, and 170 yards of open watercourse were cleansed. Five nuisances were in the course of abatement at the date of the report.

HALIFAX.—Mr. Travis gives an interesting account of his work in this borough during 1883, particularly as regards the removal of refuse. In addition to recording that the Goux system is rapidly extending, the inspector notes with satisfaction that the authority have themselves resolved to undertake the cleansing of ashpits, a step of considerable importance. During the year 10,960 loads of night-soil and 7,445 loads of refuse were collected, both figures exhibiting an increase as compared with previous reports. The streets appear to have been systematically scavenged, though the staff at the disposal of the inspector does not permit this to be done as frequently as is to be desired. As many as 2,480 nuisances were disposed of, involving the inspection of 5,600 dwellings, and the issuing of 711 notices. More than 200 houses were dealt with on account of the existence of infectious disease; but the present system of disinfection seems to be of a very partial kind, and the inspector urges his authority to no longer delay the erection of some suitable and effective disinfecting ovens.

SELBY RURAL.—Mr. Christie's report is brief; but it contains some not unimportant details. During 1883 the inspector made 425 visits, discovered 285 nuisances, and issued 152 notices. No fewer than 4,080 yards of drainage were repaired and cleansed, whilst 1,037 yards of new sanitary pipes were laid by private persons and 945 by the authority. Other items of the report refer to the building and repairing of ashpits, the cleansing of cesspools, the disinfection of houses, and the disconnection of sink-pipes.

SELBY URBAN.—For this district, which has a population of 6,029 persons and an area of 3,643 acres, Mr. Mallinson has little of interest to record. The principal event of the year, as reflected by this report, seems to have been the cleansing of 1,050 yards of Holme Dyke. But 38 notices were issued by the inspector, and 19 by the sanitary authority, for the abatement of nuisances, and it is not clear what success attended these applications. Thirteen drains were cleansed and repaired, 7 houses were provided with spouts, four water-closets were ventilated, and a few other minor improvements were effected.

TADCASTER RURAL.—Mr. Denham's report, although statistical only, contains abundant evidence of systematic and painstaking work. The year witnessed a considerable extension in the drainage of the district (3,913 yards of pipes having been laid), and in the provision of properly trapped gullies. In addition to this, a considerable number of minor sanitary improvements were effected. Thus, 109 sink-pipes were disconnected, 47 old ashpits and privies were destroyed, 468 gullies and drains were repaired, 70 pigstyes and manure heaps were removed from against dwelling-houses, and 120 houses were white-washed or stoved. In the course of the year 496 nuisances were discovered by Mr. Denham, and in all but 55 cases they were abated upon first application.

WEST HAM.—The report of Mr. W. Horn as chief inspector of this enormous and ever-growing urban district gives an excellent idea of the amount of work which the sanitary supervision of such a necessarily entails. Mr. Horn is grateful to the 'scare' for the impetus it gave to his work in the detachment of sinkpipes from drains, the removal of water-closet flushing pipes from cisterns for drinking water, and the removal of such cisterns where the water was liable to be polluted with sewer gas. More than 8,000 houses were visited in 1883, and the total number of premises dealt with amounted to 1,192. Some of these premises had to be visited half-a-dozen times before the necessary work was done. Nearly 400 special complaints of nuisances were attended to, and 410 cases of infectious diseases were reported.

The work of disinfection was lighter than in the previous years; but 163 rooms and about 5,000 lbs. of bedding and clothing had to be subjected to the process of fumigation. Sixty-two samples of food (butter, cheese, and milk) were submitted to analysis, and 14 samples for adulteration obtained. A substantial share of the West Ham sanitary staff is taken up in the provision of the offensive trades that flourish in the district.

It is satisfactory to find that Mr. Horn is fully alive to the importance of this department of his work.

NEW INVENTIONS.

MR. BOYLE'S NEW ECONOMICAL SYSTEM OF VENTILATION FOR WORKMEN'S HOUSES.

This system of ventilation has been introduced by Messrs. Boyle & Son, Ventilating Engineers, 64 Holborn, London, and Glasgow, intended for workmen's houses and

ventilation could be produced at a cost that would enable it to be applied to even the poorest houses, it would tend very considerably towards the improvement of the public health, as it is a fact well known to all medical men and sanitary officials that the pestiferous atmosphere which generally exists in the houses of the poorer classes is one of the causes of many of the diseases and fevers which perpetually haunt the more densely-populated parts of all towns. This fact, and the necessity of some economical system of ventilation, was pressed upon Messrs. Boyle's attention as far back as ten years ago by Mr. Edwin Chadwick, C.B., but they were not in a position then to act upon his suggestions. They, however, did not lose sight of the question, and only awaited the time when the public mind would be fully alive to the importance of the subject and the necessary attention drawn to it, which would enable them to submit the system with good hopes of its being adopted. That time Messrs. Boyle believe has now arrived, and the accompanying diagram shows the arrangement they propose to apply for the purpose of securing a constant extraction of the foul air and supply of fresh air to each apartment without the slightest draught being felt by the occupants, as it is a common experience that where ventilating openings are made which admit of draughts they are at once closed up and rendered useless as ventilators.

A (see diagram) is a Boyle's patent self-acting air-pump ventilator, 16-inch diameter, fixed on the ridge of the roof. This ventilator continually extracts the foul air, and is entirely free from down-draught. B, main shaft, 8-inch diameter, with divisional plate in centre to prevent the currents from the branch pipes striking each other and creating a swirl which would be injurious to the ventilation. CC, 5-inch diameter branch pipes connecting ventilator with 4½-inch flues in the walls. DD, 4-inch diameter pipes connecting upper rooms to branch pipes by means of 4-inch diameter holes cut in centre of ceilings. EE, 4½-inch flues in walls communicating with spaces, FF,

spaces of the poor. Messrs. Boyle have been long of opinion that if some simple and efficient system of ventilation could be produced at a cost that would enable it to be applied to even the poorest houses, it would tend very considerably towards the improvement of the public health, as it is a fact well known to all medical men and sanitary officials that the pestiferous atmosphere which generally exists in the houses of the poorer classes is one of the causes of many of the diseases and fevers which perpetually haunt the more densely-populated parts of all towns. This fact, and the necessity of some economical system of ventilation, was pressed upon Messrs. Boyle's attention as far back as ten years ago by Mr. Edwin Chadwick, C.B., but they were not in a position then to act upon his suggestions. They, however, did not lose sight of the question, and only awaited the time when the public mind would be fully alive to the importance of the subject and the necessary attention drawn to it, which would enable them to submit the system with good hopes of its being adopted. That time Messrs. Boyle believe has now arrived, and the accompanying diagram shows the arrangement they propose to apply for the purpose of securing a constant extraction of the foul air and supply of fresh air to each apartment without the slightest draught being felt by the occupants, as it is a common experience that where ventilating openings are made which admit of draughts they are at once closed up and rendered useless as ventilators.

GGGG, air inlet brackets, 10" x 5" x 3", one fixed in the corner of each room furthest from opening in ceiling, and about 6 feet from the floor.

Messrs. Boyle do not submit this system with the view of deriving a profit from it. It is introduced solely and exclusively for the benefit of the working and poorer classes, and with no other object, as the following figures will, we think, conclusively demonstrate, they being, we are given to understand, the *net cost* of the material and time making up same, nothing being allowed for other expenses incurred, Messrs. Boyle bearing those themselves. One 16-inch diameter Boyle's patent self-acting air-pump ventilator, made of galvanised iron, and painted, 1½ ft. 8 in. diameter pipe, with dividing plate, 30 ft. 5 in. diameter pipe, 8 ft. 4 in. pipe. Two 5-inch junctions, two 5-inch knees, two 5-inch flanges, two 4-inch junctions, two 4-inch knees, four air inlet brackets, 10" x 5" x 3". All the above, made of strong galvanised iron, is sold at four guineas complete. A plan and printed instructions is also supplied along with each set of appliances. The system can be adapted to tenements at the same rates, every room in the largest tenement being ventilated separately. It can also be applied to existing buildings at a trifling extra expense.

We think the Royal Commission on the dwellings of the poor, of which H.R.H. the Prince of Wales is so active a member, could not do better than give a little attention to this practical solution of the problem how to ensure pure air in the homes of the poor which has as yet been submitted to the public, and we hope to see others follow in the footsteps of Messrs. Robert Boyle & Son in their laudable and disinterested endeavours to improve the condition of their poorer brethren, and make their existence more bearable than it is, or ever can be, under the present conditions. Such endeavours are doing good service to the State, of which Messrs. Boyle are useful citizens.

RAYNER & CO.'S LIME-FRUIT SYRUP.

THE business of Messrs. Rayner, Farringdon Road, the manufacturers of Rayner's Lime Juice—which is one of the best of the preparations of the lime as a syrup—is about to be formed into a company for the purpose of extending the operations of the firm; the intention of the company being to acquire lime groves of their own in the West Indies, and so become growers of the fruit as well as manufacturers of lime juice. In connection with the Lime Fruit Syrup made by this firm, a letter appeared in the columns of the *British Medical Journal* of June 14 last, from Dr. John Thompson, M.D., F.R.C.S., who has been a great sufferer from psoriasis. He has found Rayner's Lime Juice the best remedy for the disease of any that he has tried, and says that he now prescribes it to all his patients suffering from this distressing skin disease, and that he is satisfied that the Lime Fruit is a valuable remedy. Doubtless Rayner's Syrup is not the only one suitable for the cure of psoriasis; but this preparation has a freshness of flavour that contrasts favourably with many others, which is probably the reason why Dr. Thompson selected it in preference to other makes.

A NEW FIRE EXTINGUISHER.

MANY inventions taking the name of 'Extincteurs' and Fire Annihilators, are now manufactured, and each of them can lay claim to different merits, but while useful for public buildings, large mansions, and generally speaking, the wealthier classes, the price of them is prohibitive to small householders. What is required is a simple and reliable appliance that shall be at all times ready for use, not requiring any supervision to keep it in working order, and that can be sold at a price the working-man can afford to pay. Such an invention, of American origin, is now under consideration; and perhaps no one but an American would

have conceived the idea of making such an appliance of an ornamental character, so that it may stand upon sideboard or bracket in a sitting-room, without attracting special notice. The Harden 'Star' Hand Grenade Fire Extinguisher, of the Company bearing that name, whose London address is Southwark Bridge Road, supplies the desiderata already enumerated. It is simply an ornamental opaque glass bottle hermetically sealed, containing on pint of a chemical fluid which when broken over fire, if in not too advanced a stage, is sufficient to completely extinguish it. It may happen that one bottle will not always have this effect; that must depend upon the progress the fire has made; but from what the writer recently saw at a public exhibition of the capabilities of this Fire Extinguisher, he was astonished at what was accomplished by the contents of one bottle, when it is pointed out that the price of this ingenious invention is only three shillings and ninepence, it may well be asked who will so neglect their own safety as to go without a fire extinguisher? A new danger is no amongst us; for whatever advantage mineral oils have provided in the shape of a cheap light-giving medium, is none the less a fact that they are constantly productive of fires, and even loss of life. During the winter month the newspapers constantly record accidents arising from the use of mineral oil lamps which, unfortunately, are mostly confined to the homes of the working class. Last winter a great deal of space was devoted in the *SANITARY RECORD* to this question, and the makers of the lower-priced kinds of lamps were asked to endeavour to introduce some contrivance by which, if a lamp was overturned, the light should be automatically extinguished. Publicity was given at that time to an invention in this direction, which there is reason to hope will be properly placed at the service of the public during the coming season. In addition to the advantages of the 'Star' Hand Grenade for temperate climates like our own, it is equally useful in any climate, as it withstands the changes of atmosphere to which it is likely to be subjected, is said not to deteriorate with age, and will not freeze 20° below zero. In the experiments witnessed, which took place in the open air, a wooden chimney about one foot square by 14 feet high, well coated inside with Stockholm tar, was set alight by a fire ignited in the lower part. When thoroughly in a blaze with about 4 feet of solid flame emerging from the top, one of the bottles was broken over the fire at the lower part, and in a quarter of a minute was entirely extinguished. A small hoarding similar to that coated with tar, and afterwards soused with petroleum was also ignited and allowed to become one mass of flame. This was extinguished by the contents of one bottle in about six seconds. Extraordinary as this may appear, the probability is that had the fluid been used for a fire in room or covered building, it would have accomplished its work in even less time, as it must be quite evident that a large portion of the gas generated must evaporate in the open, which would be retained in a closed apartment. A further advantage possessed by the fluid contained in the bottles is that fabrics of any kind are not injured by coming in contact with it, neither does it affect the floor injuriously. Thus every safeguard appears to be provided for in the 'Star' Hand Grenade, and, with one of these always standing in the principal rooms of a house, the danger of a fire proving disastrous is likely to be reduced to a minimum.

THAT excellent organisation, the New York St. John's Guild, which has been in existence since 1866, hopes to continue its excursions this summer for the benefit of its children. Last summer the floating hospital made thirty-two regular excursions and twelve extra excursions, carrying 29,189 children and mothers or guardians. The seaside nursery also did good work in keeping children several days or a week in the country. Many children with diarrhoeal diseases had their lives saved by its means.

REVIEWS.

*General Health Exhibition—Handbooks. Ambulance
isation, Equipment, and Transport.* By Surgeon-
G. J. H. Evatt, M.D., Army Medical Depart-
ment. London: William Clowes & Sons, Limited.

Dr. Evatt has written a very excellent handbook upon a subject of great practical importance. He has understood his mission in a wide sense, and, while giving an accurate and condensed account of the military ambulance systems, and War Ambulance Aid Societies of various countries, he has not failed to devote some space to ambulance systems for civil life. For any complete system of civil ambulance relief we must look abroad, not to the great cities of the United States, for in these we have no organisation by which help can be rendered in case of accident in streets or factories, but to the most modern methods of transporting the injured and to nothing like a complete system of hospital relief. Perhaps as yet regard with some natural suspicion like the scheme which Dr. Evatt believes to be the best, namely, to make the rates responsible for all expenses in hospital finances, a scheme which, we apprehend, could quickly end in making hospitals municipal institutions supported entirely by the rates; but most agree with him in believing that it would be very better for the patients if existing hospitals were into receiving hospitals where only severe cases are retained, the less severe cases and the convalescents being drafted off by ambulance trains to linked up on well-chosen suburban sites. The account given of Railway Ambulance and Sick Transport systems is doubly interesting, and the luxuries of Dr. Baron's ambulance train, the property of the Souveranen & Ritter Ordens Gross-priorat von Bohmen, will surprise those whose ideas of railway comfort for the sick have never risen above one side of a compartment train, besides the engine and guard's van, a sleeping carriage for the knights and medical staff, a store-wagon, a kitchen-wagon, with every appliance for cooking on a large scale, a dining wagon, ambulance sick transport carriages, each carrying ten patients lying on comfortable suspended stretchers, and a baggage wagon containing the linen store, and distillery. Such a train is of course the extreme of ambulance luxury, but Dr. Evatt carries the reader step by step from the most simple contrivances to arrangements more and more complicated, until Baron's train ceases to be so entirely unprecedented as it seems from our description. Dr. Evatt speaks in the most well-deserved praise of the admirable organisation of the Metropolitan Asylums Board for conveying cases to the floating hospital at Long Reach, and gives a plan and section of the ambulance steamer *Warrior*, now running on the Thames. (See EXHIBITION for July 26.) We can speak in high terms of the handbook; no subject is neglected, none treated at too great length, and all are illustrated by helpful drawings.

The following recipe for making rice-water will be useful at this season. Take a dessert-spoonful of each pint of water, let it boil three or four hours, and flavour with lemon-juice and sugar. This will at once arrest such diarrhoea as proceeds from indigestion or from slight internal irritation or inflammation, and is likewise sufficiently nourishing for persons suffering from such derangement in hot weather.

ACCORDING to the returns of the Commissioners of Inland Revenue, the consumption of spirituous drinks per head of population is still on the decline. In Scotland, however, the returns of duty on spirits consumed as beverage, on the contrary, an increase amounting last year to 33 gallons, or over 34 per cent. as compared with the year 1882.

CORRESPONDENCE.

(All communications must bear the signature of the writer, not necessarily for publication.)

SEWAGE DISPOSAL.

I have lately read several articles in the daily and other papers with reference to the fouling of the Thames by the solid matters contained in the sewage which is discharged into it.

In the year 1878 Sir Joseph Bazalgette estimated this quantity of solid matter at 88 tons each tide, or 64,240 tons per annum. Assuming an increase to 136 tons at each tide, or 100,000 tons per annum, is the drying and disposal of this quantity such an arduous task that the Corporation of the richest city in the world should hesitate to undertake it? No doubt the cost of works would be great; but nothing in comparison to the cost of conveying the whole of the sewage to the German Ocean, as well as losing 100,000 tons of such valuable material, with the certainty of its being driven back to pollute the shore.

The only article of value which science has hitherto succeeded in extracting from the sewage is the sludge itself, which, when unadulterated with chemicals, contains 2 per cent. of ammonia, and has an analytical value of 30s. to 35s. per ton. This analytical value can be easily converted into a commercial value, leaving an ample margin for profit even upon a small undertaking. Sewage sludge can be reduced to a dry powder, and be mixed with other ingredients and put into bags ready for the market at less than 7s. 6d. per ton.

There are several ways in which it can be treated and turned to profitable account. Either of the following processes could be carried out on the banks of the Thames, instead of saddling the ratepayers with a burden, which can never be removed if the alternative scheme of conveying the sewage to the ocean be adopted. The first process consists in adding sulphuric acid to the dried sludge, putting the mixture into an ordinary kind of purifier and then passing through it the gas generated from the distillation of ammoniacal liquor. The product will contain 40 per cent. of dry sulphate of ammonia, and at the present price of the materials used, inclusive of labour, the cost of production will be several pounds per ton less than the market value of the article produced.

In the second process, the dried sludge may be distilled to furnish the ammonia, in lieu of purchasing gas liquor; the cost in either case will not vary more than a few shillings per ton, the latter being, in all probability, the cheapest on account of the large volume of gas (nearly 5,000 cubic feet per ton) which would be generated and used for heating purposes, and other bye-products not yet ascertained.

In other words, 100,000 tons of dried sewage sludge can be so manipulated as to produce 26,000 tons of manure, analysing 10 per cent. of ammonia and 18 per cent. of re-precipitated phosphates, at a price that will leave a clear margin of several pounds per ton, to pay for depreciation, management and profit, when sold in competition with other manures of the same analytical value.

If any of your readers are at all sceptical on this point I shall be pleased to give them convincing proof of the accuracy of my assertions.

JOHN HOWARD KIDD,
Westminster Buildings, Wrexham.

THE COMMUNICABILITY OF ENTERIC FEVER.

Though, I fear, no longer young, as it is now fourteen years since I anxiously watched the surgeon whose pupil I was, through a fatal attack of typhoid, I am in a position similar, though not identical, with that of the 'young doctor' alluded to by M. S. E. in the SANITARY RECORD for July 15.

I entered into a friendly discussion with our sanitary inspector on an interesting and important question. I

have always repudiated the epithet 'old fogies,' which he attempted to put into my mouth, and I do not sneer at those who happen to differ from me, as I think it wrong to enter into a serious discussion in the spirit of M. S. E.

To show with what respect I treat those who hold an opposite opinion, I cannot do better than to quote the letter I addressed to the *Lancet*, together with the editorial reply.

Sir,—I lately saw two cases of enteric fever under treatment in the general medical ward of a large metropolitan hospital. I have always understood that, provided the excreta were immediately disinfected and removed, this practice was absolutely free from danger to the other occupants of the ward. Bristowe says: 'It is admitted by probably all physicians that enteric fever is not, in the usual sense of the term, contagious; that it is not conveyed from one person to another by the touch or by the breath; and that attendants on the sick rarely, if ever, take the disease from them.' In private practice I have always acted in accordance with this belief, and though I have placed before the friends the advisability of removal to a fever hospital, I have never urged it as a necessity. I have, however, heard that theory as to the mode of communication warmly disputed by men who have every opportunity of forming a decision. I should be glad if you would tell me what opinion is held by the majority of the profession on the subject. I have never seen any ill consequences arise from my procedure, even amongst the very poor; but I would gladly abandon it if I were convinced that it was fraught with danger. An authoritative statement would relieve me of much anxiety, as our medical officer of health holds a different opinion from mine.

I am, sir, yours truly,

June 23, 1884.

DILEMMA.

We should say emphatically that the majority of hospital physicians agree with Dr. Bristowe and our correspondent.—ED. L.

I am glad to see that Dr. Collie apparently agrees with me when he says:—

'And when one thinks that the infective matter of the enteric fever patient is for the most part contained in his stools; that these are passed into vessels which are immediately removed from the ward and emptied into the drains, *there remains nothing* to infect the non-enteric patients in a general ward.' [The italics are mine.]

July 22, 1884.

X. Y. Z.

HOUSING OF THE WORKING CLASSES.

*'How best to help the slender store,
How mend the dwellings of the poor?'*

WILSON'S BUILDINGS, CITY OF LONDON.—In consequence of some remarks made by a jury when investigating the circumstances of a suicide at Wilson's Buildings, Lower Thames Street, Dr. Sedgwick Saunders has recently made a special inquiry into the condition of the houses. He reports that they are a portion of an old hotel, and were purchased by the Government for the accommodation of some of the *employés* of the Custom House, fifty years ago. When no longer required for this purpose the dwellings were leased to a private person, upwards of thirty years ago, and had been let in tenements ever since. There are nineteen tenements in the block, in holdings of five of three, nine of two, and five of one room respectively, in all thirty-eight rooms, occupied by persons varying in number from fifty to sixty; the rooms are of fair size, and as a rule are, and have been, kept fairly clean. The owner is a respectable solicitor, who holds possession from the Crown, and who, Dr. Saunders reports, has never failed to fulfil the requirements of cleansing and repairing for which the sanitary department has, from time to time, served official notices. The buildings are principally built of wood and plaster, the back walls only being of brick. They comprise four tiers of apartments, approached by one

very steep, narrow wooden staircase. Four tenements only have back or through ventilation, and although the cubic contents per person of the whole of them are not far below the necessary limit, the back rooms are devoid of light, and so entirely without ventilation, that Dr. Saunders thinks them unfit for human habitation. He advises that the case should be referred to the Sanitary Committee for them to view the premises and determine what further steps should be taken either to render them fit for healthy dwellings, or to insist on such structural alterations as may be recommended.—The new town, for such it deserves to be considered, which the Improved Industrial Dwellings Company are erecting in Soho is now rapidly approaching completion; so large a portion indeed is already prepared to receive its future inhabitants that the twenty-first anniversary of the society's foundation was recently celebrated by an opening ceremony, at which the Prince and Princess of Wales presided. The precise spot is that which was very lately known as Newport Market, together with Porter Street and adjacent courts and alleys—the whole closely abutting on the line of the projected new street from Charing Cross to Oxford Street. The company acquired the land on which Sandringham Buildings stands from the Board of Works last September, since which time their official surveyor, Mr. Borer, and his foreman, Mr. Hickie, have been busily engaged in directing the operations of an army of workmen. The blocks of buildings, including the shops, will provide altogether about 1,000 rooms apportioned in separate tenements of two, three, and four apartments, the three-roomed holdings being found to be in most request, as being best suited, if not to the wants, at least to the means of the classes for whom they are intended. Although as yet only 124 sets in Sandringham Buildings are completed, Mr. J. Moore, the secretary, has already had 400 applications for them; while others are coming in at the rate of forty or fifty a day. Each set, not excepting the two-roomed tenements, is absolutely complete in itself, and provided with an outer door, neatly painted and grained, with a knocker and letter-box. Between this and the inner door is a useful space, in which is a little washhouse, with sink, cupboards, and sanitary conveniences, including a very ingenious dustshoot, which compels the inmate to burn vegetable refuse, paper, and so forth, instead of hoarding it up to breed fever, and this for the simple reason that only dust and fine ashes will go down. Inside, the apartments are prettily papered. Each kitchen has a copper and a kitchen-range, and it is an invariable rule that no room shall be without one of the fireplaces, with their really artistic little sides and chimney-pieces, which the association manufacture for the purpose. The windows are each divided into three sashes, instead of the ordinary two, the short lower division being fixed for the safety of little children. Over every door, moreover, is a swinging fanlight, so that draught is maintained at the ceiling level 8 feet 6 inches from the ground throughout every tenement. It would not be easy to give an intelligible description of the double current atmospheric system of ventilation of the closets; it is important, however, to note that every pipe throughout the blocks connected with the sewers is carried some distance above the roofs and open. The success of the 'horizontal system' of ventilation in the rooms is sufficiently attested by the fact that in no one of these vast buildings have the company ever known a case of infectious disease being communicated from floor to floor. From the health point of view it is an important fact that, precious as space is, no less than half an acre is set apart for playgrounds, not to speak of nearly a quarter of an acre more in the shape of odd bits, which are distinct additions to the breathing spaces. The company give preference to families that have been displaced by the pulling down of houses in the neighbourhood. The height of the blocks is 62 feet. All staircases are of a fireproof material, formed of consolidated coke-breeze and Portland cement, manufactured—like nearly all other materials used—by the company itself.

On the roof—the sixth landing from the ground, is a road flat space, in one corner of which is a well-fitted general washhouse—the only detail of the system which is of common use.

THE thirteenth annual meeting of the shareholders of the Newcastle-upon-Tyne Improved Industrial Dwellings Company, was held at the company's offices Newcastle, on the 25th ult., under the presidency of Mr. James Hall, J.P., the chairman of the company. The report, which was of a cheering character, and recommended the payment of a dividend of 3½ per cent., was adopted unanimously. After the re-election of the retiring directors and other formal business, the chairman said that there probably was not another company in England which carried out the spirit of the Act more completely than they did. They made it their business to furnish excellent accommodation for the genuine labouring poor; as many of the men who left their dwellings in the morning did not know whether they would be able to meet with employment for a single hour, much less for a day or a week, they were essentially giving effect to the Act. The same remarks did not apply to other companies located elsewhere, which paid better dividends. When they looked into the working of those companies which were able to pay 5 per cent., they would find that they did not accommodate the same class of labourers, which the Newcastle company did, but persons in a superior position in life. In Newcastle they found that their tenants were utterly unable to pay the high rents, which could be so readily obtained in London for similar accommodation; at the same time it should be remembered that they had to pay the same rate of interest and repayment of principal to the Public Works Loan Commissioners, as the London companies, who were so much more advantageously situated. Considering the laudable work in which they were engaged he thought that they were entitled to exemption from house duty, which pressed hard on them, and to which they had been subjected on a mere technical point, whilst most of the London dwellings enjoyed immunity from that burden. Mr. John Price, resident director, reported that the birth and death-rate for the year ending June 30 were rather 'above the average of the city, the latter arising from exceptional causes, in no way connected with the sanitary condition of the buildings—one child having fallen out of a window and was killed immediately, and some infants died very soon after birth; the general rate of mortality in the buildings since their erection being much over than that of the rest of the town during the same period. Mr. Price also stated that, being resident on the premises, he devoted several hours daily to the inspection of the water-closets, sinks, and drains, and otherwise strove all in his power to preserve the good sanitary condition of the buildings, though, as may be expected with such a class of tenants, his duties were by no means a leisurely one. The company's block comprises 108 dwellings, with an average population of 500 persons, most of the tenants being labourers, dependent on casual employment at the wharves or steamboats at the neighbouring quay-side.

At the Convocation of the Clergy of the Northern Province, held at York on the 17th ult., under the presidency of His Grace the Archbishop of York, the President, in moving 'That it is important that the clergy should take an active interest in questions affecting the homes and health of the people,' said that this question had now assumed very great prominence. The work of the clergy was only now beginning. The labourers of England were very numerous, and that fact would unhappily forbid the idea of mercenary provision of dwellings for them. What was the clergy to do in promoting health and decency? His Grace urged that sanitary associations should be formed in every town similar to that which existed at Hull; and recommended and implored clergymen, who from their position were above suspicion, to take greater interest in matters affecting the public health, and to make themselves acquainted with sanitary matters. In that way, and with

the joint action of municipal authorities, pressed on by an enlightened public opinion, a great deal might be done. The poor died by thousands for want of remedial measures. Constant pressure should be brought to bear upon public opinion and upon municipal authorities. If mothers in slums were taught that their dark, dirty, drainless, horrible dwellings were dangerous and deadly to the children whom they loved, they might move them to aspire to better dwellings and more comfortable conditions for their children. An interesting discussion followed, in which several of the leading clergy in the diocese took part. Much good is anticipated from this action of the Convocation.

PARKS AND OPEN SPACES.

*The law condemns both man and woman
Who steals the goose from off the common;
But lets the greater felon loose,
Who steals the common from the goose.*

OPEN SPACES AS PLAYGROUNDS FOR CHILDREN.—Referring to the rumour that a railway company are seeking powers to obtain the whole or part of the space known as the 'moor,' Mr. Harris, in his last report on Sunderland observes that the moor is the great resort of the children of Sunderland parish, and without it the district would suffer from a much higher mortality than at present, heavy though that may be. The moor stands much in the same relationship to the district that the lungs do to the blood circulating in the human body—it supplies it with pure air, giving tolerably free scope to the wind to sweep down and purify the stagnant atmosphere of the neighbouring streets. If the moor is ever to be changed, it should be changed not into railway sidings, or costly parks, but into a proper playground for children, in which they would not be afraid of trespassing on the grass, but where they could freely exercise their limbs, and in which the corporation should erect swings and other means of recreation as in other towns. Ornamental parks are, Mr. Harris adds, most desirable acquisitions to large towns, affording untold pleasure to the adult population, but of no service to the neglected children of the slums, who do not patronise them, but who, nevertheless, require the health-giving powers of pure air.

'OUT-DOOR SITTING-ROOMS.'—On Aug. 2 Lady Selborne presided at the ceremony of opening the St. Nicholas disused burial-ground in Wellington Street, Deptford, as a garden and public recreation ground. The Kyrle Society have borne the expense of laying out the plot, which covers about an acre of ground, and has the advantage of an avenue of trees down the centre. The duty and cost of maintaining the ground in order will be undertaken by the Local Vestry and the Greenwich District Board. The Rev. Brooke Lambert, on behalf of the Kyrle Society, thanked her ladyship for her attendance, and moved the customary vote of thanks, which was seconded by Mr. W. J. Evelyn, J.P., and carried. The churchyard of St. Peter's, Hackney Road, which has been tastefully laid out with beds of flowers and provided with seats by the Kyrle Society, has been opened as a recreation ground for the use of the public by the Bishop of Bedford. The Bishop of Bedford, in the course of a short address, expressed his gratification at the amount of pleasure which the society had been able to afford to the poor in various parts of the metropolis, by laying out and opening for their use churchyards and disused burial-grounds. He hoped the grounds he was about to open would be a place of beauty and attraction for the poor of that neighbourhood. Consequent upon the exertions of the Metropolitan Public Garden, Boulevard, and Playground Association, Ebury Square, Pimlico, has been thrown open for public use and recreation. Nearly an acre has, through the action of Lord Brabazon, Mr. Ernest Hart, and others connected with the association, been

added to the open spaces at the West End of the town, which the public may freely use.

In his last report on the sanitary circumstances of Tottenham, Dr. Tyndale Watson makes a plea for the provision of a people's park and the establishment of swimming baths. It is to be regretted, he observes, that some of the fine open fields on rising ground between Lordship Lane and Phillip Lane could not be utilised as a public park. This would form a pleasant health-resort, and if swimming baths were attached, it would be still more valuable. We hope with Dr. Watson that the suggestion may meet with a response from the inhabitants, who number nearly 66,000, and that the exercise of some public spirit may lead to practical results.

THE Arboretum at Walsall, an area of seventeen acres, eight of which are water, has been opened by the Mayor and Corporation as a public recreation ground. The price paid was £4,000, Lord Hatberton, the chief original owner, having merely charged money out of pocket. Three other grounds are to be opened hereafter—one, Reed's Wood, which was obtained from the Earl of Bradford, containing forty-six acres.

SANITARY JOTTINGS.

SANITARY.

MR. JOHN PRICE, who has been for the last fourteen years resident director of the Newcastle Improved Dwellings Company, has been invited by the committee to read a paper on 'The Housing of the Poor' at the ensuing Diocesan Conference, to be held in Newcastle on October 29 and 30.

The Local Government Board have forwarded to the Corporation of Gateshead copies of Dr. Barry's reports of the sanitary condition of the borough, with special reference to the prevalence of infectious disease in the district, and also reports and suggestions for the prevention of nuisances by the removal of refuse or excrement. The matter was referred to the Sanitary Committee. The chairman said they all knew the difficulty they experienced in getting the work done efficiently by the contractors.

CONGRESSES.

SANITARY INSTITUTE OF GREAT BRITAIN.

THE Autumn Congress, 1884, will be held at Dublin from Sept. 30 to Oct. 4, 1884. The sections of the Congress will be constituted as follows:—

SECTION I.—'SANITARY SCIENCE AND PREVENTIVE MEDICINE.'
President.—Thomas W. Grimsbaw, M.A., M.D., F.R.C. and Q.C.P.L., Registrar-General for Ireland.

Honorary Secretaries.—J. F. J. Sykes, B.Sc., Pub. Health, M.B., L.R.C.P., M.R.C.S., E. MacDowell Cosgrave, M.D.; George F. Duffey, M.D., F.R.C., Q.C.P.L.

SECTION II.—'ENGINEERING AND ARCHITECTURE.'
President.—Charles D. Cotton, C.E., M.Inst.C.E., Engineering Inspector Local Government Board for Ireland.

Honorary Secretaries.—W. R. E. Coles; J. P. Griffiths, M.Inst.C.E.; W. Kaye Parry, M.A., C.E.

SECTION III.—'CHEMISTRY, METEOROLOGY, AND GEOLOGY.'
President.—Charles A. Cameron, M.D., Sc.C.Camb., City Analyst and Superintendent Medical Officer of Health for Dublin.

Honorary Secretaries.—H. Percy Boulton, M.Inst.C.E.; R. J. Moss, F.C.S.; J. Byrne Power, D.Sc.; C. R. C. Tichborne, LL.D.

Papers and Discussions.—Authors are reminded that the acceptance of Papers, and the days on which they are to be read, are as far as possible determined by the Council before the beginning of the meeting. The Council reserve the right of refusing any Paper sent in, and in the case of those accepted, the reading of them must depend upon the time at the disposal of the Council. No previously published Paper can be read. Papers read at the Congress cannot be published by the authors, unless by permission of the Council. The Council reserve to themselves the privilege of printing any Paper read at the Congress, either wholly or in part, or of refraining from the publication thereof, if they see fit. Papers are limited to twenty minutes in reading, and the discussion upon them to ten minutes each speaker. In order to give an opportunity to the Council of doing

justice to the several communications, and to assist the Transactions, each author should prepare an abstract and send it, together with the original manuscript, by 10 or before September 1, addressed to the Secretary, Sanitary Institute of Great Britain, 74A Margaret Street, W.

Authors whose Papers have been received and accepted are furnished with printed copies before the commencement of the Congress.

NOTICES OF MEETINGS.

THE annual meeting of the Association of Municipal Engineers and Surveyors was held in the Town Hall, N. Tyne. The members assembled under the chairmanship of Mr. White, of Oxford, the retiring president. He afterwards, the president-elect, Mr. W. G. Laws, City Engineer of who, in an able inaugural address, briefly glanced at the most important matters which are now engaging the attention of Mr. J. P. Spencer, of Newcastle, read a paper on the 'Irregularities of the Sanitary Arrangement of Houses,' in which he pressed considerable doubt as to the possibility of the Sanitary Authority devoting the requisite time for a thorough examination of all the houses in their district, and therefore Sanitary Associations were a necessity to a great extent. He then gave an interesting description of what he regarded as the most efficient mode of testing drains, both by the smoke and tests. Lieut.-Col. Alfred S. Jones, of Wrexham, read a paper on 'Best Practicable and Available Means of Rendering Sewage Harmless,' which excited a lively discussion.

THE first general meeting of the North-Eastern Sanitary Association was held at their offices, New Castle, on July 17, under the presidency of Sir Ma Ridley, M.P. The chairman, in moving the adoption of the Association (which stated that 222 members had joined the Association the year), said he felt strongly the extreme desirability of such an association as this in the north of England and elsewhere. He thought they had reason to be satisfied with the work done. He was somewhat surprised that it had been so well. Landlords and tenants were bound to turn to sanitary matters—not only because cholera might be the country, but because an idea was getting abroad that to pay more attention to the health of their families and themselves. He had considerable confidence in coming to him for a report on his own house, and he hoped that they would content with anything short of annual inspections. If the newest portion of his house was in the worst condition, had no doubt others would find the same thing. Dr. Spence, in seconding the adoption of the report, quoted figures that the public sanitary officials of the county of Durham possibly make annual inspections of every house. The Corporation should welcome this association as a valuable body that they had under consideration what could be done for the poor.

COMPETITIONS.

INTERNATIONAL INVENTIONS EXHIBITION 1885.

Amongst the classes of products notified to be at this Exhibition are the following, likely to be of interest to the subscribers to the SANITARY RECORD:—

DIVISION I.—APPARATUS, APPLIANCES, PRODUCTS, INVENTED OR BROUGHT INTO USE SINCE 1865.

GROUP I.—AGRICULTURE, HORTICULTURE, AND ANIMALS.

CLASS 3.—Dairy and Poultry-farm Appliances.—Machines, cream-separators, churns, cheese-making apparatus for manufacturing butterine, incubators.

GROUP II.—MINING AND METALLURGY.

CLASS 8.—Machinery and Appliances used in Quarries.—Ventilating, lighting, aids to respiration. Life-saving appliances. Utilisation of waste.

GROUP III.—ENGINEERING CONSTRUCTION AND ARTS.

CLASS 13.—Roads.—Methods and materials for constructing roads, cleaning roads and pavements; machines; rollers; apparatus for the removal of mud, water-carts and other means of watering. **CLASS 19.—Highways and Sewerage.**—Methods of collecting, pumping, storing and distributing water; appliances for detecting and preventing water, water-meters, water fittings, filters, sewers, posals and utilisation. **CLASS 20.—Reclamation, Irrigation, Drainage of Land.**—Drainage (natural and artificial) districts, irrigation works. **CLASS 21.—Materials used in Building.**—Bricks and tiles, machines for making them; concrete, stone, cement, materials and appliances used in their preparation, roofing felt, and other roofing materials, cables and other applications of metal in building; appliances for cottages, buildings; preservative and fire-resisting materials.

for application to stone, wood, iron, &c., methods of applying the same. CLASS 24. *Building Construction*. Models and plans showing methods of construction, non-combustible constructions, labour saving and other machines and appliances used in building, scaffolds, elevators, fittings and appliances used in buildings. CLASS 25.—*Heating, Ventilation, House-drainage, &c.*—Sanitary appliances: ventilators, cowls for chimneys, chimney-sweeping apparatus, apparatus for heating by steam, water, air, &c., means of cooling air.

GROUP IV.—PRIME MOVERS, AND MEANS OF DISTRIBUTING THEIR POWER.

CLASS 26.—*Steam-engines and Boilers*.—Methods and appliances for preventing explosions, and for testing boilers, fire-grates, fire-fuelers, smoke-consuming appliances, pumps.

GROUP VI.—COMMON ROAD CARRIAGES, &c.

CLASS 36.—*Bicycles and Tricycles*.—'Cycles' of every description, and fittings for the same.

GROUP XI. HYDRAULIC MACHINES, PRESSES, MACHINES FOR RAISING HEAVY WEIGHTS, WEIGHING, &c.

CLASS 59. *Pumps, hand, steam, rotary, centrifugal*. Ships' pumps, pumps for corrosive fluids, hydropulps, syphons, methods of raising water, methods of obtaining, distributing, and equalising hydraulic power: accumulators. CLASS 60. *Fire-engines*. Fire-extinguishing apparatus: automatic apparatus for indicating and extinguishing fires, fire-escapes, ladders, fire-hose, accessory fittings and appliances: hydrants.

GROUP XIV.—APPARATUS, PROCESSES, AND APPLIANCES CONNECTED WITH APPLIED CHEMISTRY AND PHYSICS.

CLASS 76. *Inorganic Products, and means used in obtaining them*.—Sulphuric and other acids, alkalies and ammonia, bleaching agents, dyes and dye-stuffs, salts, white lead, pigments, and other pigments, phosphorus, lucifer matches, disinfectants. CLASS 70.—*Organic and Synthetical Products, and means used in obtaining them*.—Coal tar products, oils, soaps, and detergents, lubricating agents, candles, perfumery, paraffin, varnishes, manures.

GROUP XV.—GAS AND OTHER ILLUMINANTS.

CLASS 81.—*Coal Gas*. Manufacture, purification, storage, and distribution of gas, treatment of residues. CLASS 82. *Water Gas, Oil Gas, Carburetted Air, &c.* CLASS 83.—*Tests and Photometrical Apparatus*. Chemical tests, standards of light measurement of light. CLASS 84.—*Burners, and means of Utilising and Applying Gas*. Gas fittings, burners for illuminating gas, devices for imparting luminosity to flame, gas-meters, methods of lighting gas, methods of increasing illuminating power of gas. CLASS 85. *Mineral and other Oils*. Methods of obtaining, distilling and refining, testing. CLASS 86. *Candles, &c.* Candles of wax, tallow, sperm, paraffin, &c., nightlights, appliances used in the manufacture. CLASS 87.—*Lamps for Oil and Spirits, Holders for Candles, &c.*

GROUP XVI.—FUEL, FURNACES, &c.

CLASS 88. *Manufacture of Fuel*.—Materials and processes for the manufacture of artificial fuel, preparation and use of liquid fuel, preparation of peat, charcoal burning. CLASS 89.—*Furnaces for Manufacturing Purposes*.—Furnaces for burning solid, pulverised, liquid and gaseous fuel. CLASS 90. *Stoves for Coal, for Gas, for Oil, &c.* Cooking stoves and kitchen ranges, domestic fire-places, gas cookers, gas burners for heating and cooking, petroleum and other stoves for heating and cooking.

GROUP XVII. FOOD, COOKERY AND STIMULANTS.

CLASS 93.—*Preserving Food*.—Methods, materials, and processes for preserving animal and vegetable food, machines for producing cold. CLASS 94.—*Bread and Biscuit Making*.—Kneading machines, biscuit and bread-making machines, ovens, processes for making bread. CLASS 95. *Cooking Apparatus*.—Culinary utensils, chopping and mincing machines, apparatus for paring and slicing fruit and vegetables, cleaning fruit, washing and cleaning vegetables. CLASS 96.—*Brewing, Distilling, and Wine-making*. Machines and appliances connected with the manufacture and use of alcoholic drinks. CLASS 97.—*Manufacture of Aerated Waters*.—Machinery, materials, &c., used for the purpose. Stoppers and other appliances. CLASS 98.—*Infusions*. Apparatus, &c., used in the preparation and use of tea, coffee, chocolate, &c.

GROUP XVIII.—CLOTHING.

CLASS 100. *Fabrics*.—Specimens of new materials, or materials recently applied to the manufacture of clothing. CLASS 101.—*Articles of Clothing*.—Specimens of clothing of novel construction. CLASS 102.—*Cleaning Clothing*.—Washing and wringing machines, wringing, &c., machines, boot-cleaning machines, machines and processes for cleaning other articles of clothing.

GROUP XX.—LEATHER.

CLASS 107.—Methods of waterproofing, &c., leather.

GROUP XXI.—INDIA-RUBBER AND GUTTA-PERCHA.

CLASS 110.—*Applications of India-Rubber and Gutta-Percha*.—Waterproof goods.

GROUP XXII.—FURNITURE AND ACCESSORIES. —FANCY GOODS.

CLASS 113.—*Floor-coverings and wall-coverings (other than Paper-hangings)*.—Oilcloth; linoleum, kamptulicon, mats and matting; material, appliances, and processes used in their manufacture.

GROUP XXIII.—POTTERY AND GLASS.

CLASS 120.—*Bricks, Tiles, Earthenware, &c.*—Architectural pottery; fire-clay goods; drain-pipes.

GROUP XXVI.—PAPER, PRINTING, BOOKBINDING STATIONERY, &c.

CLASS 137.—*Machines and Processes for the Manufacture of Paper, Paste-board, and Papier-Mâché*.—Paper, recovery of waste products, and preventing the pollution of streams.

GROUP XXXI.—TOYS, SPORTS, &c.

CLASS 163.—*Toys, Games, and Exercises*.—Gymnastic apparatus.

THE INSTITUTION OF CIVIL ENGINEERS.

THE Council have awarded the following Premiums in respect of the Original Communications referring to Sanitary Subjects submitted during the Session 1883-84:—

The Manby Premium to George Henry Stayton, Assoc. M. Inst. C.E., for his Paper on 'Wood Pavement in the Metropolis.'
A Telford Premium to William Santo Crimp, Assoc. M. Inst. C.E., for his account of 'The Wandle-Valley Main Drainage.'

APPOINTMENTS UNDER THE PUBLIC HEALTH ACT.

MEDICAL OFFICERS OF HEALTH.

BRYDEN, Robert Thomas, L.R.C.P. Edin., L.R.C.S. Edin., has been re-appointed Medical Officer of Health for the Windhill Urban Sanitary District, Yorkshire, at £35, for one year.

BUCHANAN, Dr. Peter, has been appointed Medical Officer of Health for the Coleford Urban Sanitary District, Gloucestershire, at the rate of £20 per annum until March 25 next, *vice* Hatton resigned.

DONOVAN, Denis Dempsey, L.R.C.P. Edin. and L.M., L.R.C.S. Edin., L.A.H. Dub., has been re-appointed Medical Officer of Health for the Cork Urban Sanitary District, at £150 per annum, *vice* Cremen, resigned.

FLETCHER, Charles William Corrie, L.R.C.P. Edin., and L.M., M.R.C.S. Eng., has been re-appointed Medical Officer of Health for the Willington Quay Urban Sanitary District, at £40 for one year.

HARRIS, Charles, M.D. Univ. St. And., M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the No. 2 Division of the Rye Rural Sanitary District, at £75 for one year.

LOYD, William Howell, M.R.C.S. Eng., L.S.A. Lond., has been appointed Medical Officer of Health for the Llando Fawr Rural Sanitary District, Carmarthenshire, at £50 per annum, *vice* Jones, deceased.

LUNDY, Louis Francis, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Staines Rural Sanitary District, at £75 for one year, from Aug. 11.

MACGREGOR, George Robert, M.D. Univ. Aberd., has been re-appointed Medical Officer of Health for the Wilden Urban Sanitary District, Yorkshire, at £20 for one year.

MASON, George, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Wisbech Urban Sanitary District, at £40, for the year ending June 24, 1885.

PALEY, William Edmund, M.B. Durh., L.R.C.P. Lond., F.R.C.S. Eng., has been re-appointed Medical Officer of Health for the Peterborough Rural Sanitary District, at £100 for one year.

PHILLIPS, Edward England, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Southend Urban Sanitary District, at £15 per annum, for three years.

POLLARD, William Robert, M.R.C.P. Edin., L.R.C.S. Ire., has been re-appointed Medical Officer of Health for the Church Urban Sanitary District, Lancashire, at £20 for one year.

SHORTIDGE, Thomas Wood, L.R.C.P. Edin., L.R.C.S. Edin., has been re-appointed Medical Officer of Health for the Honiton Urban Sanitary District, at £25 for one year.

SKINNER, Robert Vale, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the No. 3 Division of the Rye Rural Sanitary District, at £15 for one year.

STOTT, Hugh, M.R.C.S. Eng. and L.M., L.S.A. Lond., has been appointed Medical Officer of Health for the newly-formed Friern Barnet Urban Sanitary District, at £37 for one year.

TAYLOR, Dr. Shephard Thomas, has been appointed Medical Officer of Health for the newly formed Cromer Urban Sanitary District, at £15 per annum.

THOMPSON, Abram, M.D. Univ. St. And., M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Ulverstone Rural Sanitary District, at £133 per annum, for three years, from Sept. 30 next.

WALKER, John McClure, M.B., C.M. Univ. Glas., has been appointed Medical Officer of Health for the No. 2 Division of the Alston-with-Garrigill Rural Sanitary District, at £20 per annum, *vice* Pickworth, whose appointment has expired.

WOODHAMS, John Amor, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the No. 1 Division of the Rye Rural Sanitary District, at £20 for one year.

SURVEYORS, CLERKS TO GUARDIANS, INSPECTORS OF NUISANCES, &c.

BLIK, Mr. Thomas John, Solicitor, of Middlesbrough, has been appointed Clerk to the Eston Local Board and Urban Sanitary Authority, Yorkshire, at £60 per annum.

BROOKS, Mr. Walter, Assoc. Mem. Inst. C.E. (Chief Assistant to Mr. E. B. Ellis Clark, Mem. Inst. C.E., Surveyor and Engineer to the Hove Urban Sanitary Authority), has been appointed Surveyor to the Richmond Urban Sanitary Authority, Surrey, at £200 per annum, *vice* Bruston, whose appointment has expired.

BURTON, Mr. Samuel Garvey, baker, has been appointed Treasurer to the newly formed Cromer Local Board and Urban Sanitary Authority.

BYFIELD, Mr. George Dickinson, has been appointed Clerk to the Friars-Barnet new Local Board and Urban Sanitary Authority, at £200 per annum.

CLARK, Mr. George, has been appointed Surveyor to the Friars-Barnet new Local Board and Urban Sanitary Authority, at £200 per annum, Inspector of Nuisances at £75 per annum, and collector at 1 per cent. commission.

CROSS, Mr. John, manager of the National and Provincial Bank of England, Leeds, has been appointed Treasurer to the Leeds Guardians and Rural Sanitary Authority, *vice* Hornsby, resigned.

CURRY, Mr. William, has been appointed Surveyor, Surveyor of Buildings, Inspector of Nuisances, Manager of the Waterworks, and Superintendent to the Fever Hospital, to the Bedlingtonshire Local Board and Urban Sanitary Authority, Northumberland, at £100 per annum, *vice* Rimmer, resigned.

DAVIDSON, Mr. Robert, has been appointed Surveyor, Inspector of Nuisances, and Collector to the Howdon Local Board and Urban Sanitary Authority, at £15 per annum, *vice* Paul, resigned.

DIGBY, Mr. William King, has been re-appointed Treasurer to the Corporation and Urban Sanitary Authority of Maldon, Essex, at £30 per annum.

EGGAR, Mr. Robert, of the Halifax and Huddersfield Union Bank, Halifax, has been appointed Treasurer to the Northowram Local Board and Urban Sanitary Authority, *vice* Bowman, deceased.

EVANS, Mr. W. Scott, has been elected a Member of the Berne-mouth Board of Improvement Commissioners and Urban Sanitary Authority, *vice* Elwyn, resigned.

FRANK, Mr. R. has been appointed Collector to the Eton Local Board and Urban Sanitary Authority, at £35 per annum.

HANSELL, Mr. Peter Edward, has been appointed Clerk to the newly formed Cromer Local Board and Urban Sanitary Authority, at £35 per annum.

HEATON, Mr. C. W., F.I.C., F.C.S., has been re-appointed Public Analyst for the Parish of St. Martin-in-the-Fields.

HEWITT, Mr. C. G., has been elected a Member of the Gainsborough Local Board and Urban Sanitary Authority, *vice* Platt, appointed Inspector of Nuisances.

HOWAR, Mr. Henry, the Surveyor to the Aylesbury Local Board and Urban Sanitary Authority, has been re-appointed Inspector of Nuisances until December 31 next.

KEMP, Mr. John, has been appointed Surveyor to the Haverhill Local Board and Urban Sanitary Authority at £90, and Inspector of Nuisances at £50, both for one year, with the prospect of an additional salary as Manager of the Gas Works, both *vice* Coates, resigned.

MALLOD, Mr. Horace, has been elected Chairman of the Lytham Board of Improvement Commissioners and Urban Sanitary Authority, *vice* Pilling, resigned.

MINGEY, Mr. Robert, has been appointed Surveyor to the Midgley Local Board and Urban Sanitary Authority, Yorkshire, at £50 per annum, *vice* Fletcher, deceased.

MILES, Mr. John, has been elected Chairman of the Friars-Barnet new Local Board and Urban Sanitary Authority.

MOORE, Mr. F., of the National Bank of Wales, has been elected Treasurer to the Bridgend and Cowbridge Guardians and Rural Sanitary Authority, *vice* Llewellyn, deceased.

MURKIN, Mr. William, has been re-appointed Inspector of Nuisances for the Walker Urban Sanitary District, Northumberland, at £70 per annum for three years, from June 1915, but sanctioned by the Local Government Board only for one year.

NEWMAN, Mr. John, has been appointed Surveyor to the newly formed Cromer Local Board and Urban Sanitary Authority, at £50 per annum, Inspector of Nuisances at £50 per annum, and Collector at £10 per annum.

POTTER, Mr. Edwin William, has been elected a Member of the Lytham Board of Improvement Commissioners and Urban Sanitary Authority, *vice* Pilling, resigned.

POWELL, Mr. William, has been appointed Road Surveyor to the Corporation and Urban Sanitary Authority of Croydon, at £90 per annum, rising to £100, *vice* Harlock, resigned.

RICHARDSON, Mr. William, has been appointed Clerk to the Oundle Guardians and Rural Sanitary Authority, at £75 per annum as Clerk to the Guardians, and such further salary as may be fixed from year to year, as Clerk to the Rural Sanitary Authority, to the Assessment Committee, and to the School Attendance Committee, and less as Returning Officer and Superintendent Registrar of Births, &c., *vice* Mr. Robert Richardson, his father, deceased.

ROBERTS, Mr. R., has been elected Chairman of the Wellington, Salop, Board of Improvement Commissioners and Urban Sanitary Authority, for the coming year, *vice* Slaney, resigned.

ROPER, Mr. George, has been appointed Surveyor to the Newbold and Dunsdon Local Board and Urban Sanitary Authority, Derbyshire, at twenty-four guineas per annum, *vice* Gould, resigned.

SCOTT, Mr. Walter, has been appointed Surveyor and Inspector of Nuisances to the Corporation and Urban Sanitary Authority of Ripon, at £120 per annum, *vice* Harrison, resigned.

SHEDDEN, Mr. John, has been re-appointed Inspector of Nuisances for the Long Eaton Urban District, Derbyshire, at £45 per annum.

STAMP, Mr. William Charles Hunsford, has been elected a Member of the Hove Board of Improvement Commissioners and Urban Sanitary Authority, *vice* Holford, resigned.

STOCK, Mr. Henry Porter, has been appointed Treasurer to the Friars-Barnet new Local Board and Urban Sanitary Authority.

TAPPER, Mr. Charles, has been re-appointed Inspector of Nuisances for the Dewlish Urban Sanitary District, at the same salary as before, for two years.

THOMAS, Mr. William Roach (Messrs. J. Backhouse & Co., Insurers), has been appointed Treasurer to the newly-formed Eton Local Board and Urban Sanitary Authority.

WAKELYN, Mr. Henry Charles, has been appointed Town Clerk and Clerk to the Urban Sanitary Authority of Colchester, at £50 per annum as Town Clerk and Registrar of the Courts of Record, and £25 as Clerk to the Urban Sanitary Authority, with £50 as Clerk to the School Attendance Committee, *vice* Platt, resigned (but who retains office as Solicitor to the Corporation).

WATSON, Mr. Isiah, has been elected a Member of the Colne Local Board and Urban Sanitary Authority, *vice* Catlow, resigned.

WHITE, Mr. William Owen, has been appointed Inspector of Nuisances for the Banbury Rural Sanitary District, at £10 for one year, *vice* Morrison, deceased.

WILSON, Mr. Jacob, has been appointed Treasurer to the Booth Guardians and Rural Sanitary Authority, *vice* Grice, resigned.

WINTON, Mr. Charles, has been appointed a Sanitary Inspector (additional) for the Parish of St. Pancras, at £90 per annum, rising to £100.

WITNEYCOMBE, Mr. Edward George, has been elected a Member of the Ilfracombe Local Board and Urban Sanitary Authority, *vice* Gould, appointed Surveyor.

VACANCIES.

MEDICAL OFFICER OF HEALTH for the Nottingham Urban Sanitary District: £500 per annum.

MEDICAL OFFICER OF HEALTH for the New Forest Rural Sanitary District: £100 per annum. Application, 15th inst., to William Coxwell, Clerk to the Authority, Totton, Southampton.

MEDICAL OFFICER OF HEALTH for the Eton Urban Sanitary District.

TREASURER to the Corporation and Urban Sanitary Authority of Wigan: £500 per annum. Applications, 15th inst., to Mahell William Pearce, Town Clerk.

TOWN CLERK and CLERK to the Urban Sanitary Authority of Wallingford.

ACCOUNTANT to the Corporation and Urban Sanitary Authority of Batley.

SURVEYOR and INSPECTOR OF NUISANCES to the Ely Local Board and Urban Sanitary Authority.

SURVEYOR and INSPECTOR OF NUISANCES to the Clevedon Local Board and Urban Sanitary Authority. Applications (stating salary required), 3rd inst., to Henry Charles Fry, Clerk.

INSPECTOR OF NUISANCES and SCHOOL ATTENDANCE OFFICER to the Kildersmore Rural Sanitary District: £100 per annum, from year to year. Application, 15th inst., to Frederick Burden, Clerk to the Authority.

CHIEF INSPECTOR OF NUISANCES for the Kingston-upon-Hull Urban Sanitary District: £450 per annum. Application, 15th inst., to C. S. Todd, Town Clerk.

INSPECTOR OF NUISANCES for the Doncaster Rural Sanitary District.

COLLECTOR of Rates and Water Rates to the Eland Local Board and Urban Sanitary Authority, Yorkshire: £75 per annum. Application, 15th inst., to Thomas England, Clerk, Town Hall Chambers, Halifax.

LOCAL INTELLIGENCE.

The Local Government Board, in pursuance of the powers given by the Alkali, &c., Works Regulation Act, 1862, have appointed Alfred Cooper Fryer, Doctor of Science, to be an inspector under the said Act to assist in the execution of its provisions, subject to the direction of the chief inspectors, and of any inspector under whom he may from time to time be placed.

FAIRBANK HARNET has been constituted a Local Government District with a Board of nine Members, viz. Messrs. George Abden, John George Brix, John Cleavelly, Edmund Dixon, Edward Peter Egan, Bowler Goddard, John Miles, Thomas James Phipps, George Sydney Waterlow.

Dr. Henry C. Libbey, the Medical Officer of Health for the Hove Urban Sanitary District, lately resigned because the Authority declined to increase his salary from £15 to £30 per annum. A special meeting was then held for the purpose of making an appointment, and Dr. Charles Jack, of Hove, and Dr. Libbey (who proposed to undertake his duties again at the former salary) were candidates. The voting was even, and, as the chairman could not take the responsibility of giving a casting vote, no appointment was made.

The Brampton Guardians and Rural Sanitary Authority have been invested with the powers, rights, &c., of an Urban Sanitary Authority, under Sect. 39 of the Public Health Act, for providing and maintaining urinals, water-closets, earth-closets, privies, and urinals, and other similar conveniences for public accommodation, within the contributory place of Brampton.

The Chertsey Rural Sanitary Authority have, with the sanction of the Local Government Board, increased the salary of the Inspector of Nuisances £50 per annum.

The Stafford Rural Sanitary Authority at their meeting on July 5 received and read a letter from the Local Government Board (in answer to the resolution reported in the *SANITARY RECORD*, July 5, page 42) stating that 'they, too, had only arrived at their decision

15. State the advantages or disadvantages of a self-pipe fitted by way of a funnel with any cover with which you are acquainted.

16. In the country it is very common to find houses, the inmates of which are obliged to rely entirely upon rain-water. How would you compute the quantity of rain water available for their use, and what size of tank would it be necessary to provide with a given superficies of roof? As rain-water is very frequently impure, how would you filter it - i.e. before it entered a cistern in the roof and soil, before it entered an underground tank? Sketch any apparatus with which you are acquainted, which for a few minutes catches the impurities from the roof and delivers them into the common drain before delivering water into the drain leading to the rain-water tank.

17. Supposing that you were called to a house where an infectious disease had prevailed, and the house was vacated, how would you proceed to disinfect it, beginning with the basement and ending with the top story - and what disinfectants would you use? What do the various disinfectants do?

18. Sketch any illuminating gas regulator with which you are acquainted and describe its action.

19. You are called to a house and you are asked to show that there is no escape of illuminating gas. What steps would you take to satisfy yourself and your client as to the condition of the pipes, and on what indications, other than those of the sense of smell, would you rely in testing the soundness of the pipes?

NOTES AND QUERIES.

Having for some time back been in the receipt of Queries appearing strictly to sanitary work, and which it would be easy to answer, without having to refer our correspondents to competent professional advisers, we have opened a column in which to register such Queries and Replies thereto as can fairly be expected from us - and our subscribers and readers are invited to make such use of this column as will tend to benefit themselves and the community. Both Queries and Replies will, however, be subjected, if unnecessarily long, to a strict curtailment.

106. LEGAL DEFINITION OF 'INFECTED' CLOTHING.

That part of the Public Health Act, 1875, relating to the exposure of infected persons and clothing, and generally in regard to infectious disease, has long been regarded as anomalous if not defective, and Mr. Harris, in a recent report on the health of Sunderland, draws attention to a question in relation thereto which we believe has never before been discussed. He asks whether the word 'clothing' in section 146 of the Act does not properly include the clothing worn by persons living in the same room or premises as the patient, and explains the circumstances which led him to bring the subject forward. It seems that up to October of last year he was enabled to keep in check, in the face of very defective hospital accommodation, the spread of small pox by informing the members of the family of an infected person, who had no proper means for isolation at home, that it was essential for the public safety that they should alert to remain altogether in or out of the house, and that they could not be allowed to mingle indiscriminately with the public, while so virulent a disease as small pox remained unisolated at home. It was explained to them that the members of the family when going to and from their work would almost to a certainty, convey the infection to others, and they were also informed of the penalties attaching to an offence of this character. (Section 146 of the Public Health Act, as it well known, imposes a penalty of five pounds on any person who 'gives, lends, with, transmits, or exposes, without previous disinfection, any bedding, clothing, rags, or other things which have been exposed to infection from any dangerous infectious disorder.') In October, Mr. Harris, considering that certain three persons had not proper means of isolation, informed the parents as above, and the patients were then removed to hospital at the request of the parents, who were given ample time to consider their course of action. Serious objection was taken to the health officer's procedure by the medical attendant, who complained to the Town Council. The Council appealed to the town clerk for an interpretation of the law, and he held that Section 146 of the Public Health Act did not apply to clothing worn by persons living in the same room or house. In consequence of this Mr. Harris had to cease his line of action, and was thus deprived of his most potent weapon for preventing the spread of the disease, which immediately made rapid strides.

(Viewed in a general sense, the town clerk's reading of the section is no doubt correct, for what is required to be proved is that the clothing has in fact been infected. It is doubtful whether the friends of a patient ill with infectious exanthema can be required to stay at home, but, on the other hand, there can be little question that the clothing of persons who are in close contact with those already attacked may become infected, although the difficulty of proving this would probably be a bar to successful proceedings for exposure. If, however, this can be satisfactorily shown, the section is, in our opinion, distinctly applicable. As Mr. Harris observes, there is no doubt that if any person carried away company, without previous disinfection, articles of wearing apparel which had been lying about, or hanging in, the infected room, that person would be subject to a heavy penalty - but, according to the local interpretation of the word 'clothing,' if the same person had lived in the midst of infection, and had afterwards mixed with the public, although dressed in the very clothing which he had worn in the sick room, that this person would not be liable to punishment. In

other words, clothing seems to be clothing when it is so this is so, the wearer the clothes is attended the better, conscious to think that anyone and other persons who employed, or who live in infected houses where there are of inmates, should be allowed to wander about according own not even will without changing their wearing apparel escape punishment for spreading disease. As we have often mention is applicable when evidence is forthcoming of the having been infected; but the wording can be obviously at the better. - E.O.]

107. COMPULSORY REMOVAL TO HOSPITAL.

While upon the question of the imperfection of the clause Public Health Act with reference to infectious diseases, I will to direct attention to the need for amendment in the of Section 146 of the Act with regard to the power of its removal of persons. Under this section, Any person suffering from any dangerous infectious disease, and is lodging or accommodation, or lodged in a room occupied than one family or is on board any ship or vessel, a certificate signed by a legally qualified medical practitioner removed by order of a justice in any infectious hospital or have been provided in the district. In the year 1879 the W. Corporation obtained powers under their local Act the procedure as to compulsory removal in such a way assistance of a justice's order is only to be called into it when the person to whom notice has been given refuses removal of the sufferer to hospital definitely refuses to a such removal. The object of the clause is no doubt to prevent delay and difficulty which now often arise in obtaining a order for compulsory removal. It so happens that the clause based upon the Warrington provisions found in the Borough Police and Health (Scotland) Bill, a measure by the Lord Advocate to apply to all boroughs of more than 10,000 inhabitants. At first sight the clause appears unobjectionable but the medical officers of Health of Glasgow, Greenock, a borough, who have remarkably had much practical experience matter, unanimously condemned it as unworkable. Prob condemnation of it arose in part from the cordial agreement obtained in their districts between the health officers and the police. This cordiality does not, unfortunately, exist throughout the country, and we not seldom read only health officers of the trouble and delay caused by the in obtaining a justice's order. The clause imposes an onerous stage before forcible removal is attempted, and so far its a laudable one. The objections to the clause appear to be chiefly from the fear that delay in removal will be caused. It is, of course, highly important that when a sudden outbreak dangerous infectious disease arises, the very promptness should be taken for limiting the spread of the disease. T notices, however, contemplated by the section (which, no give in the appearance of delay) might apparently be met difficulty to follow each other at the expiration of a few hours there would certainly not be more delay in such a way under the present system requiring a justice's order other words in the 'Warrington clause' without a accommodation proper for the treatment of the case, and for the purpose of isolation, which make clear a point the much canvassed, viz. whether the words 'proper lodging accommodation' are intended to mean 'lodging and accommodation proper for the patient himself, or proper for those around him. Any improvement in the present unsatisfactory words general Act cannot but be regarded as an advance in equity of case, in connection with this matter, the Edinburgh Local Act the power of removal solely in the medical officer of health, who has responsibility, and there is no appeal from his decision public at Edinburgh appears to have acquiesced in it for last twenty years, during which time the clause has worked public advantage. It may be necessary, however, for working of compulsory removal that the medical officer of sanitary inspector should have the power of forcing an infectious disease cases or is suspected to exist or this in the clause would be quite useless. This does not as provided for by the existing statute law. If the person of having disease or those in charge of him refuse submit medical officer of health it would frequently be impossible any certificate at all, and proceedings would thus be stayed outset. It would be well, therefore, to give the medical health and sanitary inspector a power of entry, such as given in sect. 69 of the Greenock Police Act, 1877. I have, we are informed, been found at Greenock of the possible service in the prevention of the spread of disease.

108. CASERT BEATING A NUISANCE.

The carpet-beating case reported in your columns of January 11, p. 306) is one of special interest to most sanitary districts. It is greatly to be regretted that the premises invariably productive of annoyance, if not of actual injury cannot be restrained by the local authorities, and the aggrieved persons the necessity of resorting to legal aid. Could not the difficulty be met on the part of the authorities by laws, prohibiting the beating of carpets whole or any part of their districts? - E.O.]

(It is very uncertain whether this can be effected, the view that the practice has been held to be only a public and not a public nuisance. Nevertheless, it is open to a authority to set apart a spare plot of land for the purpose this necessary operation, and to provide regular management. - E.O.]

ORIGINAL PAPERS.

PARLIAMENTARY SESSION OF 1884.

For those who gauge the success or failure of a session by the number of Acts that are added to the labours to what is euphemistically called the 'Book.' To such restless mortals the results of the present year will prove a disappointment; and we can well imagine the Minister of the Interior with a fine scorn at the modest quarto that contains the General Public Acts of the year 1884. There is abundant food for the contemplation of the set of volumes that are at large, without which no library that self considers its shelves complete. Compared with that 'bulwark of English liberty,' the Statute Book, which is always conspicuously distinguished by the binding of Volume I., one's eye passes over the simple and uncomplicated measures of the legislative cravings of the Plantagenets, and Stuart periods. It is not until the reigns of the Georges that 'Acts' begin to fill the brain; but it is reserved for the nineteenth century to crush us utterly with Parliamentary legislation. One feels it necessary, indeed, to take a deep breath of the number of volumes added for the treasuring up of the many Acts to which her present Most Gracious Majesty has affixed her sign manual. Far be it from me to attempt the hopeless task of inquiring how far the tower of legislation has been beneficial, much better we all are for it. But without the length of the Earl of Wemyss and the effluence of the League, one may indulge in a little scepticism as to the usefulness and even the necessity of a good many of the measures that have received the Royal Assent.

THE METHODS OF LEGISLATION.

Legislation now-a-days is to be snippety. A difficulty crops up in the working of the law that can only be effectually remedied by further legislation. An enterprising Minister in this circumstance an opportunity of distinction. He introduces a Bill. The House is talked about; his name appears in the newspapers. The Government want an evening for a pose he obligingly gives way, after promising that facilities shall be afforded for the consideration of the important measure. The House has taken charge; and in the fulness of time, the Bill is passed. The Minister may or may not probably the latter be his bantling safely through the shoals and reefs of Parliamentary progress. In this way the variations of important general Acts, the law and help to spoil its efficacy. For a very familiar instance, the Public Health Act of 1875 is currently regarded as our sanitary code. But it was tinkered at in 1876 as regards canal boats, again in 1878 as regards the law in 1879 as regards interments, again in 1880 as regards laws, again in 1883 as regards the law and now in 1884 as regards proceedings of the law forbidding officers of local authorities to be concerned in contracts. And the same said of other branches of legislation. We have no time to take up a subject in and grapple intelligently with the problems. We have never patience to construct an edifice upon one uniform plan:

we run up a flimsy erection of the 'jerry-building' order, and when its flaws become revealed we patch it up according to the fancy of the workman who happens to be nearest at hand. This is not as it should be; but to hope for better things is evidently futile whilst Parliamentary institutions endure in their present form.

PUBLIC ACTS OF THE LAST SESSION.

The impotence of the Legislature to perform its allotted task is, however, an oft-told tale, which no words of ours are likely to remedy. We pass, therefore, in accordance with our customary plan, to sketch briefly the measures that have passed the fiery ordeal of both Houses this session, and now add refugence to the majesty of English law. It requires some dexterity to discover any Bills that escaped the parricidal knife during the general massacre consequent on the fate of the Franchise Bill in the Lords; and of the few that have survived we are not sure that their sacrifice with the others would have been a source of unmixed grief. For with the solitary exception of the Canal Boats Bill, which really appears to be a useful measure, they all deal with some minute detail of sanitary procedure that was certainly not pressing, and would best have been dealt with as part of a general Act. It would be beyond our province to speculate how much more might have been done if the Franchise difficulty had not disturbed the calculations of those unhappy beings whose business it is to attempt to find time for everything, with the natural result of finding time for nothing. Subjoined is, however, the outcome from a medico-sanitary point of view of five months of the hardest work that members of the House of Commons have ever had to bemoan:—

*Canal Boats Act (1877) Amendment Act (Royal Assent, Aug. 14).—*The object of this Act is to remedy certain defects which had been observed in the working of the principal Act of 1877. Thus the registration of a boat under sect. 1 of the Act of 1877 having been found to be often a mere farce, and to have been regarded as covering a boat though reconstructed and altered, sect. 1 of the new Act provides that the certificate of registration shall cease to be of force in the event of any structural alterations having been made affecting the conditions upon which the certificate was obtained. The penalty clauses of the principal Act being imperfect, sect. 2 imposes a fine of twenty shillings on the master and owner of the boat for default in complying with any of the regulations of the Local Government Board and Education Department. No central control over the working of the Act by local authorities being provided for in the principal Act, registration, in the sense of control, of canal boats had come to be a dead letter in many parts of the kingdom. Accordingly sect. 3 enacts that 'it shall be the duty of every registration or sanitary authority within whose district any canal or any part of a canal is situate, to enforce within such district the provisions of the principal Act and this Act, and any regulations made thereunder by the Local Government Board.' Every such authority must, within the first twenty-one days of January in each year, make a report to the Local Government Board as to its proceedings during the preceding year for the enforcement of the law as to canal boats. Sect. 4 requires the Local Government Board to make an annual report to Parliament as to the execution of the Acts, and to cause inquiries to

be made from time to time by an inspector or inspectors to be appointed for the purpose. Such inspectors may hold formal inquiries, and call for witnesses and papers, and 'may enter any canal boat at any time by day (defined by sect. 9 to mean between 6 A.M. and 9 P.M.), and examine the same and every part thereof, and may, if need be, for the purpose of such inquiry, detain the boat, but for no longer time than is necessary.' The master must produce his certificate to the inspector, and furnish him with all the assistance he wants. Refusal to comply with the inspector's requisitions will be regarded as 'obstruction,' to be punishable by a fine of forty shillings. The Education Department may make regulations as to the attendance at school of canal-boat children (sect. 5), and are each year to report to Parliament how the Education Acts are enforced with respect to such children (sect. 6). In order to be 'lettered, marked, and numbered' in conformity with sect. 3 of the principal Act, a canal boat must be lettered, marked, and numbered on both sides, or in some suitable position on the stern of the boat, so as to be plainly visible from both sides of the canal.

Cholera, &c., Protection Act (Royal Assent, Aug. 14).—This is a short measure of two clauses, the *raison d'être* of which is not specially clear. It provides that where a sanitary authority in Ireland is empowered to acquire a site for a cholera or other hospital within its district, it may, with the sanction of the Local Government Board, exercise such power 'without, but contiguous to, such district' (sect. 1). Whenever the Irish Local Government Board directs any urban authority to superintend and see to the execution of regulations which otherwise would be the duty of any Board of Guardians, the sanitary authority may insert a separate item for the necessary expenditure in any rate required for the purpose (sect. 2).

The Cholera Hospitals (Ireland) Act (Royal Assent, Aug. 14) is virtually a re-enactment of the Act with the same title passed in the session of 1883. It provides that, on receiving a certificate from a medical officer that a case of cholera has occurred, it shall be lawful for the authorities of a sanitary district, having first obtained the consent of the Local Government Board, to take possession for a temporary hospital of any site within that sanitary district (sect. 1). It is to be sufficient notice to the owner or occupier to affix a notice on the walls of the union or any church or chapel in the district, or to post a copy of the notice to the occupier (sect. 2). No site is to be taken which is within 300 yards of a dwelling-house without the consent of the occupier (sect. 3); and not more than two acres may be taken for any site (sect. 5). The owner or occupier may be granted such compensation as the Local Government Board may award (sect. 4). The Act expires on May 1 next (sect. 7), and it is to be hoped that meanwhile some more practical legislation on the subject may have been inaugurated.

Disused Burial Grounds Act (Royal Assent, Aug. 14) forbids for the future the erection of 'any buildings upon a disused burial ground, except for the purpose of enlarging a church, chapel, meeting-house, or other places of worship.' This Act, which was promoted by Mr. Holland, will put a stop to burial-grounds being disposed of in the future as eligible building sites, as was recently the case at Bethnal Green.

Public Health (Confirmation of By-laws) Act

(Royal Assent, May 18).—This is a pure Act with regard to the confirmation of made under various Acts of 1847 as to houses, hackney carriages, bathing, and the like. *The Public Health (Ireland) Districts Act* (Royal Assent, Aug. 14) makes provision as to the recovery of the district, property, debts, and the like, in any urban sanitary district in Ireland that has been dissolved or for any cause ceases to exist.

The Public Health (Members and Officers) Act (Royal Assent, Aug. 14), provides that provision for the recovery of any penalty under Section 1 of the Public Health Act of 1875 from officers or persons in authority interested in any bargains made, shall not be taken except with the sanction in writing of the Attorney-General.

The Valuation (Metropolis) Amendment Act (Royal Assent, March 28), gives greater facilities for the recovery of the valuation lists in the case of owners who fail to pay the tenants' rates and taxes, more especially when the houses are subdivided into tenements separately rated.

We have no space to do more than mention the names of the other public Bills of the session. The Bill failed to secure Her Majesty's autograph. Mr. Waugh's *Copyhold Enfranchisement Bill*; Mr. Cameron's *Disposal of the Dead Bill*, which evoked an interesting discussion on cremation at its second reading, was negatived on April 11. Mr. Monckton's well-intentioned but impracticable *House Inspection Bill*; Sir John Lubbock's Bill for extending the provisions of the Factories Act to shops; the triad of measures introduced by Mr. Broadhurst, Lord Randolph Churchill, and Mr. Charles Ross to put a stop to the iniquitous practice of life leases, on which we commented at length in the SANITARY RECORD for April 15 last; Mr. Vernon's *Medical Acts Amendment Bill*, a very useful piece of legislation, which for two years has been paralysed by the selfishness of the medical corporations; Mr. Cowen's *Municipal Corporations Bill*; Mr. Warton's *Patent Medicines Bill*, introduced on March 26, in view of a promise by the Government—never fulfilled—that they would introduce a measure of their own; Mr. Dodd's *Public Health Acts Amendment Bill*; the Government Bill for creating a Secretary of State for Scotland, which would have taken over, amongst other things, the control of poor law, lunacy, public health, rivers, rivers pollution, adulteration, artisan trades, and other business of Scotland; Mr. Warton's absurd *Shop Hours Regulation (Liverpool) Bill*, which proposed to shut up every shop in Liverpool except milkshops, tobacconists, refreshment houses, and druggists for the whole of Sunday, from 8 P.M. every day, except Saturday, when it was to be shut at 2 P.M., under a penalty of 10s. for each offence; Mr. Stratheden and Campbell's *Smoke Nuisance Bill*; Mr. Peter Taylor's Bill for the removal of the compulsory clauses of the Vaccination Act; Mr. Reid's *Vivisection Prohibition Bill*; Mr. Dodd's and Mr. Henderson's *Waterwork Bills*.

UNSUCCESSFUL PUBLIC BILLS

WITH this paltry result ends a session which was more hopefully than any of its immediate predecessors in the promise of some efficient legislation on the subject of public health. For, indeed, altogether of Sir William Harcourt's oft-quoted London Government Bill, there was a du-

early in the session of a measure to reform the bottom local government generally; and the situation of London, threatened with disestablishment, had prepared a highly popular measure to pare the claws of the metropolitan water companies. These three measures all came to an end. The first did not even reach its second reading, though its advocates profess to regret that it was not carried. The second, though it had a majority of 188 to 117 on a motion for adjournment as pledging the House of Commons to the principle of the Bill. The second never saw the light, and the third was thrown out (admittedly not on its merits) by a majority whose common-sense was borne in by the cry of confiscation. Nor must we mention the Lord Advocate's Bill for the amendment of the Police and Sanitary Law of 1862: a measure equally remarkable for its size, position, and its inherent absurdity.

London Government Bill was the first of two measures for the reform of local government introduced in the Queen's Speech and in subsequent declarations of Ministers. Whilst Sir William Hartnell professed his inability to deal with certain reforms in the administration of the metropolis, on the plea that this would properly form the duties of the new Central Council that was to be created by his Bill, Sir Charles Dilke was in favour of the consideration of State subventions to the metropolis by the promise of a Bill which would alter the whole constitution of local authorities.

The latter measure never got further than Sir Charles Dilke's tantalising sketch of it; but the Secretary's Bill, after three years of gestation, was brought forth to a dazzled community on the 10th of March.

Sir William Harcourt proposed to incorporate as a single municipality all the inhabitants of the metropolitan area as defined by the Act of 1855, to confer on the new municipal body all the rights, powers, property, and obligations belonging to the Corporation, the Commissioners of Sewers, the Mayor, the Court of Aldermen, the Common Council, the Wardmote, the Metropolitan Board of Works, the magistrates of Middlesex, Kent, and within the specified limits, the Burial Boards, Vestries. Only three points were reserved: law administration, elementary education, and police. The Common Council, containing representatives for the City and 38 other existing parishes, was to be permitted to delegate its minor powers to local elected Boards; the Lord Mayor and the Deputy Mayor were to be paid officials; the Corporation were to disappear.

During the time for some little time, meetings for and against the Bill were organised in the City of London, and there is unfortunately no doubt that many, if not most, of the meetings were packed. But apart from the noisy knot of agitators who exercise their lungs at these gatherings, there is a widespread feeling amongst the more intelligent classes of the community that some reform of the London Government is urgently called for. These classes now to bestir themselves, and since the Cabinet that the question is one that is regarded as urgent. The people who have up to now sent raised their voices in favour of reform adequately represent those who are anxious to get the better and more intelligent to take an interest in local affairs.

Home Secretary's Bill was not perfection,

but it contained the elements of a good working measure, and nothing can well be worse than our present system of vestry mismanagement. The debate on the second reading of the Home Secretary's Bill brought out very remarkably the weakness of the case against it. Nearly all the antagonistic speeches belonged more properly to the Committee stage, which the Bill was never destined to reach. Not even the Lord Mayor, despite his picturesque determination earlier in the year to 'fight the Bill line by line,' had anything effective to say against the Bill: and there can be little doubt that had it been possible to get the verdict of the lobbies upon the Bill, its principle would have been affirmed by a substantial majority. It is idle to speculate as to the extent of its mutilation in Committee. The measure afforded a fair target for the attacks of a practically unlimited number of members ambitious of distinction, for local government is just one of those things upon which every man regards himself as a superior authority. We can only hope that the Bill may be reintroduced next year at a very early date, and promptly referred to one of the Grand Committees who had so easy a time of it last session. But with the shadow of the Redistribution Bill upon us it would be unwise to speculate very hopefully upon the chances of any useful legislation of this kind next year.

The Burgh Police and Health (Scotland) Bill was a very extensive and pretentious Bill introduced by the Lord-Advocate, apparently under the auspices of an obscure organisation known as the Royal Convention of Scottish Burghs. The Bill was of the paste-pot and scissors order, and had evidently been drafted by someone who did not in the least understand the subject on which he was working. The original draft of the Bill when first introduced in 1883 was received in Scotland with a shout of derision, some faint echoes of which were wafted south of the Tweed; and, although in the interval certain of the more flagrant absurdities had been expunged, the Bill in its revised shape of 1884 was still a masterpiece of bungledom. Although not so irrepressible and troublesome as their Irish brethren, Scotch members have a quiet persistent way of their own which enables them to get in fact, if not in word, a very workable Home Rule of their own, so that English members seldom care to interfere with whatever Northern legislators regard as helpful to their division of the kingdom. Moreover, the very bulk of the Bill itself—it weighed nearly two pounds and a quarter avoirdupois, and consisted of 558 clauses—was enough to deter any but the most voracious of amendment-movers from grappling with it. So the Lord-Advocate, anxious to see something passed, got a tired House one night to assent to the second reading, on the plea that it would be thoroughly considered by a representative Select Committee. Accordingly, a Committee was appointed. It consisted almost exclusively of Scotch members, of whom it is no disparagement to say that few have yet earned Parliamentary laurels. Undeterred by the heat of the weather, the Committee pressed gallantly through the 238 pages of the Bill, and knocked off its 558 clauses in seven sittings. Vainly were they told by the Parliamentary Bills Committee of the British Medical Association that the Bill contained clauses providing for the compulsory notification of infectious disease throughout Scotland by medical men—a requirement concerning which the profession had

a fair right to be heard; that many of the clauses of the Bill were unnecessary in view of existing legislation; that other clauses—taken hap-hazard from local bills—were senseless when divorced from their surroundings; that others again were duplicates couched in slightly varying language; and that generally the Bill needed careful consideration in view of the evidence which was proffered with regard to it by experts and the leading sanitary authorities of Scotland. The Committee decided to deliberate in private, and refused to hear any evidence. They 'revised' the Bill, and took out some of its grosser absurdities; but left it on the whole a more objectionable measure than before. They made the appointment of sanitary officers an annual one; they dispensed with any notification of disease by the occupier, and cast the entire burden upon the medical man, who, 'provided his diagnosis was found by the medical officer to be correct,' was to get half-a-crown for his certificate. It was felt to be necessary that some vigorous effort should be made to stop legislation of this sort; and accordingly the Parliamentary Bills Committee of the British Medical Association took measures for enlightening the House generally as to the character of the measure. The Lord Advocate pressed the Bill forward to the utmost of his power; but though he was successful in getting it reached one night, he had two days after to announce the impossibility of proceeding with it, in view of the opposition which it had excited. An amended consolidated Public Health Act for Scotland appears to be much needed, as the last general Act on the subject was passed in 1867; but it is to be hoped that in preparing it the Lord Advocate will turn a deaf ear to the siren voice of the Royal Convention of Scottish Burghs.

In the *Metropolis Water Bill* there was a certain element of amusement, for the City Fathers, whilst protesting with all their might against any meddling interference with their own vested rights, were posing as the people's champions in promoting legislation of the most confiscatory sort against the water companies. Not that the last-named organisations would have deserved any sympathy if the Corporation proposals had been carried into effect. Far from it. It would be a pity if their interesting pavilion at the International Health Exhibition, and the beauty of the fountain displays for which they provide the funds, were to blind the public to the extremely selfish and narrow-minded way in which they have administered the monopoly which the foolishness of Parliament in the past has given into their hands. The City Bill proposed simply that a consumer might require a supply of water for domestic purposes to be furnished to him by measure; but the charge by measure was only to come into force after a certain quantity—sufficient for ordinary requirements—had passed through the meter. But it also proposed (and here was the rub) that all new shares or stock of the companies should be offered by auction or tender; thus putting a stop to the quiet allotments at par of shares that are immediately entitled to a dividend of 10 per cent. or more, for which it is needless to say, the unhappy householder has to find the funds. There was much cry when this Bill came up for second reading about the widow and the orphan, and solemn bargains with the companies, and the rest of the cant of 'confiscation.' In the end Mr. Octavius Coope, the chairman of one of the water companies, led a sympathetic and emotional

majority into the lobby, and the good intentions of the Corporation were thus brought to nought. The water companies have not, however, had an altogether rosy time of it during the session. Awkward questions have been asked as to their intakes and the sewage of the Lower Thames Valley; the leading journal has teemed with correspondence on the subject of water rates; the victorious Mr. Dobbs has been addressing public meetings in the vain hope of getting them to understand the technicalities of the case that he so gallantly took to the House of Lords; enterprising householders have worried the hard-worked police magistrates for interpretations of abstruse sections of Acts of Parliament, and generally the companies have had, always excepting the chorus of admiration of their South Kensington enterprise, hardly a dog's life of it.

Their adversaries in Parliament have given them no peace, for in both Houses Bills were presented with the object of settling the amount of the claim for water services which the law authorises the companies to make. The Earl of Camperdown made a spirited effort to get them to declare themselves; but, unfortunately, he was bowled over on the ground of non-compliance with those awe-inspiring mysteries known to the vulgar as the 'Standing Orders.' His Bill proposed that the water companies should send in either quarterly or half-yearly, to every person liable to the payment of water rates for domestic purposes, a claim or demand note, containing the particulars by which the sum total claimed is made out, including the annual value on which the percentage charge is levied; and that not until such claim had been delivered should payment by the consumer become due. No supply of water was, moreover, to be cut off unless the water company had obtained an order granted on a summons to show cause why the supply should not be cut off, such order to state when the cutting off may take place, as well as the reason for putting the power in force. Another Bill, introduced into the Commons by Mr. Torrens, Mr. Sclater Booth, and a number of metropolitan members, proposed to give legislative endorsement to the principle laid down as regards a single company in the Dobbs' case—viz., that 'the annual value of the tenement supplied with water in the 68th section of the Waterworks Clauses Act, 1847, should mean the "net annual value" to be settled from time to time by the local authority as duly constituted.' But this Bill, like many others, was sacrificed at the shrine of electoral reform.

PRIVATE LEGISLATION OF THE YEAR.

Notification of Infectious Disease.—The line of demarcation which separates public Bills from private ones is not seldom very difficult to define; and if a judgment may be formed from the legislative products of the last few years, we should be inclined to say that so-called private legislation is getting to be quite as important as, if not more important than, public legislation. It lacks, moreover, the safeguard of publicity that in a measure controls the latter, and as a consequence the mass of local variations of general statute law that have crept in under the cloak of private Bills has come to be simply appalling. It appears impossible to rouse the House of Commons to a sense of its responsibility in this matter. The hour of 'private business' is by universal consent voted a nuisance and a bore, and to serve on a Committee on a local Bill is

d as the most tiresome of the *désagrémens* to the duties of a legislator. This is not to gird at the inefficiency of a chance conation of half a dozen country gentlemen to a lengthy and complicated private Bill upon its. Our present system of private Bill ion stands self-condemned. Owing chiefly exertions of Mr. Craig-Sellar, the House is ly awaking to a sense of its incapacity to th the intricate problems of the hundreds of Bills which the buoyant hopes of promoters annually to their notice. When Mr. Dodson that 'something must be done,' it is fair to that the leaven of Mr. Craig-Sellar is per- g the House, and that when it can find time her distractions it will make a beginning of ng the Augean stable in its midst.

of course idle to expect that any set of men, r well-intentioned, will go deliberately out of y to give themselves more work. Hence, when mbers who found themselves upon the rota

Talbot's Committee on Police and Sanitary tions came fairly to appreciate the work them, they naturally declined to vex them- about the theoretical objections to this or al proposal. They had referred to them all s (twelve in number) that contained powers

to police and sanitary regulations which d from, or were in extension of, or repugnant general law. They sat thirty times, and were t heartily glad to finish and to endorse their n's draft report. Their governing idea seems : been that you might propose what you liked ay of spending money so long as you paid ur loan in a given number of years, and that wanted further sanitary powers you must at Mr. Sclater Booth's Committee of 1882 n pleased to designate as permissible.

lon, Dewsbury, and Jarrow astutely repro- hese clauses, and the Committee passed them thusiasm. Brighton at first wanted to have sory notification of infectious disease, but re- after a town's meeting in opposition at the

Lord Redesdale, through whose hands first went, declined to allow the clauses to ng; but Mr. Talbot's Committee was more sant, and struck them out with alacrity.

same Committee at the previous sitting had lly obliged the good people of York to the entire series of Sclater-Boothian clauses, hey did not want, and which had found no

the Bill as drafted and locally approved. ng to the best-received versions of this

inary proceeding, a prominent member of omitee—much interested in the question of ion—asked the counsel for the York Bill

Sclater-Booth's clauses were not included easure, and was informed that they had not about it. To the same member's suggestion

se clauses should be inserted, the counsel, aturally anxious to curry favour with the tee, effusively assented; and thus York finds dled, without its knowledge and without its

to compulsory notification of infectious and the rest of it. It was too late to organise osition, as the Bill had passed its final ore the Committee's report on it was made

And this is the way we make laws in the lf of the nineteenth century.

the York proceedings fresh in their minds ey passed their general report, we hardly

see how the Committee can conscientiously say that they 'have not considered it their duty to impose upon the promoters of Bills' the model clauses of 1882. Nor can we, with the example of the Committee itself before us, find much hopefulness in their suggestion that another Select Committee should be appointed to consider whether there should not be a general Act amending and consolidating the laws relating to police and sanitary regulations. Some such inquiry is certainly needed, but a Royal Commission would be by far the best medium for collecting the information and sifting the evidence which is now at hand for the purpose. There is one paragraph of the Committee's report with which, however, we find ourselves able very thoroughly to agree. They say: 'It is obvious that these are matters of the highest moment to the rapidly-growing communities whose wants are every year pressed upon Parliament; and whilst recommending the consideration of these subjects in a general manner, the Committee would strongly advise that, pending the enacting of such a measure, care should be taken in succeeding sessions to control the attempts which local bodies not un-naturally make to arm themselves with powers which the law has not yet sanctioned.'

The net result of the Committee's labours, so far as concerns the compulsory notification of infectious cases and the other clauses that follow in its train, is that at three fresh towns concurrent notification by the occupier and by the medical man may now be put in force. These towns are Croydon, Dews-bury, and York. Brighton might have made a fourth, but withdrew at the last moment.

Open Spaces.—A good many of the railway and other Bills of the year contained as usual clauses for swallowing up without adequate compensation bits of commons and waste land and other open spaces, the loss of which would one day, if not immediately, be bitterly deplored. Thanks to the energy of the Commons Preservation Society, the Metropolitan Boulevard and Playground Association, and kindred bodies, these things are better looked after now than they were a few years ago, and the first-named society, in its annual report recently issued, fairly takes credit to itself for snatching from the insatiable maw of the railroad monster common land and open spaces that would else have been assimilated without let or hindrance. Perhaps the Parks Railway Bill could hardly be properly regarded as an invasion of open spaces, though there were not wanting people who questioned the efficacy of the proposed system of ventilating the line, and prophesied that eventually the detested blowholes would have to be allowed in the parks. Mr. Boyce's well-intentioned Access to Mountains (Scotland) Bill did not reach a second reading, but a modest little measure, promoted locally, has effectively preserved the Malvern Hills from the encroachments that threatened to spoil their beauty as one of our national breathing-places. (See SANITARY RECORD for April 15 last.)

Salt Works and Cement Works.—It is not often that Provisional Order Bills excite the imagination, but two of the sixty-four Bills of this class—which afford profitable employment for the junior members of the Ministry—contained some points of interest. The one proposed to confirm the Provisional Order of the Local Government Board, dealing with the question of the sewerage of the Lower Thames Valley, and was thrown out by the Select Com-

mittee appointed to consider the subject. The other, passed on July 28, deals with the regulation of salt works and cement works, and confirms a Provisional Order made by the Local Government Board in this behalf on April 10 last. This Act provides that the owners of all salt works shall adopt the best practicable means for preventing the discharge into the atmosphere from the furnaces or chimneys of such works of the muriatic acid gas evolved in such works, or for rendering such gas harmless or inoffensive when discharged. Every salt work must be carried on in such manner that in each cubic foot of air, smoke, or chimney-gas escaping from the works into the atmosphere there shall not be contained more than one-fifth of a grain of muriatic acid gas. The owners of all cement works must adopt the best practicable means for preventing the discharge into the atmosphere from the furnaces or chimneys of such works of the noxious or offensive gases evolved from such works, or for rendering such gases harmless or inoffensive when discharged. The penalty for non-compliance with these regulations is, in the case of the first offence, 20*l.*, and in the case of every subsequent offence 50*l.*, with a further sum not exceeding 5*l.* a day.

PRACTICAL BENEVOLENCE.—Lady Goldsmid and Miss Montefiore have for the third time given special donations to the Women's Protective and Provident League for the hire of a seaside house, at which the members of the various Women's Unions, formed under the auspices of the League, can spend a holiday at small cost. The committee of the League have in consequence taken a furnished house at Brighton, within three minutes' walk of the sea, for seven weeks, from Aug. 9 to Sept. 27. The charges fixed for members of Unions are 3*s.* to 4*s.* a week for bedroom, use of sitting room, and attendance; to friends of members (women) 5*s.* and 6*s.* Visitors are expected to make their own arrangements as to board, which is easy enough in Brighton, where food of all kinds is abundant and reasonable in price. The value of change of air and scene to the hard-working sempstresses and workers at various trades who compose the Union cannot be overrated, and the beneficial effects of these agents are greatly enhanced by the comfort and privacy of such a temporary home, in contradistinction to the bustle and frequent want of cleanliness and order met with in low-priced lodgings at the seaside. The unobtrusive and womanly kindness of Lady Goldsmid and Miss Montefiore are worthy of all praise, and are a delightful illustration of the grand precept, 'Do as ye would be done by.' An excellent sanitary agent in the shape of a Swimming Club has also been established by this Women's League, and is very well attended and greatly appreciated by the members of the Unions. The club meets at the Whitfield Street Baths, Tottenham Court Road, the admission to which, by special arrangement, is twopence. Six swimming lessons may be obtained for 3*s.*, and at the end of the season a competition takes place for prizes given by friends of this excellent little society, which is quietly sowing good seed in a variety of directions, moral, social, and sanitary.

The New York City Board of Health has adopted an ordinance forbidding the use of any tap, faucet, tank, fountain, or vessel, or any pipe or conduit in connection therewith, for storing beverages for drinking, which shall be composed of or made with brass, lead, copper, or other metal or metallic substance that is or will be affected by liquids so that dangerous, unwholesome, or deleterious compounds are formed therein or thereby, or such that beer, soda-water, syrups, or other liquid, or any other beverage, drink, or flavouring material drawn therefrom shall be unwholesome, dangerous, or detrimental to health.

SANITATION AT THE N ADMIRALTY AND WAR OF

By HENRY M. MAVOR.

IN looking through the various competitions for these important buildings, now at 18 Spring Gardens, it will be noticed that sanitary arrangements have in some received more preliminary attention than bestowed in many former cases. It is hitherto only too general to leave the matter to the last moment, and to call in special assistance at the eleventh hour, who then are fain to suggest structural alterations to enable the main points to be adopted. These alterations, great in themselves as to a certain extent, and often the cause of vexatious delays, have been avoided if due thought had been given in the first place. This, happily a thing of the past, and the public buildings now erected where the design is not made by the architect for the sake of and elaboration of the entire scheme. Modifications, as the work proceeds, may be made to suit the special circumstances arising; but, on the whole, if a successful result is obtained by the short means. In the example before us the designers of the building, and, subject to necessary modification, it will be seen that the principles have been recognised, and will be operation throughout.

As regards the heating and ventilation, each floor will have a space or more in depth between the floor and ceiling; in these channels wrought-iron steam pipes will be carried. Near the ceiling will be an engine-room with fan chamber, air being introduced through gratings, and spray to four powerful fans capable of circulating air twice in the hour all over the building. Purified cold air will then be carried to the channels before mentioned, where heated by being driven over the hot pipes. These channels flues of calculated area, carried to the rooms and corridors, having openings both at the floor and ceiling for winter and summer ventilation. Openings to the room from these flues, adjustable valves to regulate the admission of air. By these means all the rooms will be air forced into them by the fans, and as a consequence the vitiated air will be drawn up smoke flues (the draught of which will be thereby) and also up the foul-air shafts. The latter will have regulating valves with damp flaps to prevent any back draught; the inlet openings will be greater than that of the outlet, so that the amount of air may be increased in velocity.

The foul-air shafts will communicate with trunks in the attics, these trunks will deliver into foul-air chambers, centrally placed. Each of these foul-air chambers power ventilators will be connected, and as the air is driven into the rooms, the foul air will be displaced, assisted by the air-pump and upcast foul-air shafts.

The lavatories and water-closets will be

to the north or east, so that the sun may not be on the soil-pipes; these soil-pipes will be in chases formed in the outside of the walls of equal temperature, and will be ventilated throughout their length, the system adopted being 'combination' type, having mica valve inlets and outlets, the latter delivering above the roof, and away from any of the attic dormer windows.

The type of water-closet apparatus will be on the 'lipped' principle, and all the traps will be ventilated. The lavatories will be simple in construction, having discharge valves, and marble or slate tops, and will be trapped and ventilated to prevent syphoning. The waste-pipes will be carried inside the building (to prevent freezing); but will be ventilated throughout their length, delivering into discharging traps at foot, and communicating with the atmosphere above the roof level. The urinals on the lipped cradle principle, with self-acting mechanism for flushing purposes, the wastes being carried from any other part of the system, and down in the same chases in the outside of the walls, as those provided for the soil-pipes. The wastes will also be ventilated and disconnected from the drains, in a similar manner to that adopted for the lavatory wastes.

The housemaids' closets will be fitted with instantaneous water-heaters, due precaution being taken against risk of fire, and means provided for carrying off the products of combustion. The water-supply system will be treated on principles before de-

scribed. The lavatory room, walls, and ceilings will be of glazed bricks, and the floor tiled, so that the whole can be washed readily. Ventilation of these particular places will require attention. Each series of rooms being one of two, the authors have arranged that each shall have an extract ventilation shaft delivering into the foul-air chambers in the roof, the exit of foul air being further facilitated by extraction. Fresh air will be supplied direct from the street, though probably in winter it may be advisable to pass the air over disconnectable coils of pipes to prevent the effects of frost.

The system of proposed drainage is based upon the principle that all drains without exception should be separated, having inlet and outlet for air, and disconnected from the sewer, the rain-water, soil, and gas pipes also being disconnected from the drain, connecting traps likewise being ventilated. As indicated on the plan, each series of soil-drains will be flushed twice a day by automatic flushing arrangements.

The rains passing through the building will be of iron, treated with the Bower-Barff process (for prevention of rust), the joints being leaded.

The question which has given rise to a certain amount of controversy is that of direct external ventilation to a considerable portion of the building, as first mentioned by Mr. George Godwin, senior editor of the *Builder*, in a letter to the *Sanitary Record* in which he says, 'I am impelled to trouble you with a few lines on one most important part of the plan—I allude, of course, to the arrangement of windings around a closed central court about 100 feet long and 80 feet wide. Your own criticisms of other journals have already pointed out the comparative narrowness of this court, and the serious character of this arrangement has

not been dwelt on. I have no hesitation in saying that if this proposed plan be carried out, the building will be a most unhealthy one, to use the mildest term. The court during a large number of days in the year will be a tank of stagnant air, and no arrangement for separately ventilating the numerous apartments around it will suffice to prevent the evil it will do. The health of the majority of the occupants, day after day, of the various apartments will be gradually deteriorated, and the weakly will die off.'

None can gainsay Mr. Godwin's great experience in such matters; but, also to use the mildest term, we venture to say this is an extreme view. In the first place, the angle of 45° reaches the lowest window, and the angle of 60°, at which the direct rays of light enter, is well into the court; so much for 'light,' which goes hand in hand with 'natural ventilation.' In the same letter it states, 'every new street shall, unless the Metropolitan Board of Works otherwise consent in writing, have, at the least, two entrances of the full width of such street, and shall be open from the ground upward. Yet here we are to have what is tantamount to a new street, surrounded by exceptionally high buildings, closed not alone at one end, but at both ends, under Imperial sanction.'

Here we appear to have the gist of the matter, as this court or street is not closed at each end, but two large open gateways are necessarily required and shown on the ground plan. These openings will serve as inlets to create a considerable draught of air to prevent the 'stagnation in the tank,' and instances of the disagreeable strength of such a draught are by no means wanting. This would then appear to meet the further statements that 'the laws of nature do not change' and 'no opinion will affect the laws which regulate the movement of air.' These considerations have probably not escaped the notice of the examining committee, in which it must be remembered are two architects not unknown to fame. It has also been suggested that the height of these archways should be increased by an open columnar arrangement above them, and although this would entail a slight loss of space, it would have the effect of 'making assurance doubly sure,' and certainly not detract from the architectural appearance of the *façade*.

In questions of this description it is always well to 'err on the side of precaution,' and Mr. Godwin has done well to enter a protest against undue fulfilment of conditions which are for all time, and to bring discussion to bear upon the subject of prevention instead of cure, but it is by no means hazardous to venture an opinion that in this, as in other respects, profiting by past experience, and taking the exigencies of the site into consideration, the sanitary conditions will be met satisfactorily.

The last new thing in advertising is said to be a paper pad shirt. The bosom of this peculiar form of cheap garment consists of seven layers, of which one can be removed every day, on the blotting-pad principle, exposing a clean white surface in its place. It is further proposed to print instalments of a sensational novel of thrilling interest on the back of each of the layers, in the hope, probably, that after once beginning the tale, the wearer of the paper pad shirt will be tempted to peel off the successive layers of his shirt front in order to reach the denouement of a tantalising plot! It is not stated whether this is an American invention, but probably it is so, from beginning to end.

THE POLLUTION OF THE RIVER LEE.

AT this dull season of the year, the censorship of editors of the daily newspapers over the letters admitted to their columns is apt to get somewhat relaxed. Hence the public has been confused, and not a little startled, at certain descriptions in the *Times* of the insanitary state of the River Lee, which may well lead the average reader to the belief that all the conditions but one for a very promising outbreak of cholera, exist in the water taken from that stream for domestic use by a large section of the population of London. We can easily imagine a drinker of East London or New River water conjuring up the most frightful fancies as to the morbid qualities of that liquid after a perusal of his morning's paper, and even the happier mortal whose cistern is furnished from the pellucid Thames, may well have felt a thrill of sympathetic horror. Now the Lee is fortunate amongst rivers in having a sanitary engineer (Major Lamorock Flower) devoted to the preservation of its virtue. This gentleman perambulates its watershed perpetually, knows every little ditch that is dignified by the name of tributary to it, and generally devotes his best energies to keeping it as pure as possible. And Major Flower's opinion evidently is that, with one exception, to be presently referred to, there is no ground for the allegation that the Lee is polluted by sewage above the intakes of the two companies which draw their supply from it. The fact is that the complainants in the *Times* have confused the issue by writing as though the admitted and flagrant pollution of the lower reaches of the river was a danger to the water supply of a considerable part of London. This is from the nature of things impossible; and in what follows we shall attempt to separate the two things as far as possible from one another.

I. First, then, as to the Lee in its potable relations with the community. A full third of the water supply of the metropolis is derived from the Lee. The New River Company takes about twenty million gallons a day from it, and the East London Company about thirty-two million gallons. The Lee Conservancy Board have powers not only, as in the case of the Thames Conservancy Board, over a strip of land ten miles wide on either bank of the river, but over the entire watershed, which extends over something like 600 square miles. Under the powers of the Lee Conservancy Act 1868, it is unlawful to open any sewer into the Lee or any of its tributaries; to suffer any sewage to flow into the Lee or tributaries through any sewer; to open any sewer into any ditch or channel communicating with the Lee or tributaries; or to suffer sewage to flow into any such ditch or channel. The penalty for infraction of this regulation is 100*l.*, and 50*l.* a day afterwards. To place any manure heap, or collection of offensive or injurious matter, so that it can drain into the Lee or tributaries, is punishable by a fine of 10*l.*, and 5*l.* a day afterwards. And to throw into the Lee or tributaries any dead animal, filth, or other noisome thing, or wash or cleanse therein any animal, cloth, wool, leather, or skin whatsoever, is punishable by a fine of 5*l.*

If worked at all conscientiously, and there is abundant evidence of Major Flower's energy in getting nuisances abated, these stringent prohibitions ought to effectually purify the river. But this same Act of 1868 is unfortunately hampered by exemptions which the Conservancy Board are power-

less to alter, and which have given them abundant trouble. Thus Luton, with a population of 20,000, is specially permitted by sect. 101 of the Act of 1868 to discharge the effluent from its sewage works into the Lee after the sewage has been subjected to certain chemical processes. To the credit of the Luton authorities, however, it should be stated that the clarified effluent of the chemical process is passed over land previous to the discharge of effluent into the Lee, and pollution from the town is thereby abated. A recent analysis by the consulting chemist of the Lee Conservancy Board of the water of the river above Ware Lock may usefully be subjoined. Against it has been placed for comparison an analysis of East London water from the company's main at White Horse Street, Stepney, collected on the same day in last January:—

	Grains per gallon.	
	Ware Lock.	Stepney.
Solid matter	25.9	24.5
Loss on incineration	2.8	2.1
Ammonia.....	.0021	.0021
Ammonia from organic matter0042	.0042
Chlorine	1.4	1.435
Nitrates	Trace	None
Phosphoric acid	None	None

Both samples are described as clear and inodorous, and there is evidently nothing to choose between them.

But the chief danger to the purity of the Lee water is derived from the sewage effluents at Hertford. Hertford disposes of the sewage of its 7,500 inhabitants by precipitation, and, like Luton, it has a special clause in the Act of 1868 permitting it to discharge the effluent into the Lee under certain conditions. These conditions the Conservancy Board considered had been infringed, and accordingly they entered an action against the Corporation. This trial came on not long ago before the late Mr. Justice Watkin Williams, and provoked during the fourteen days that it lasted the usual conflicting evidence from so-called 'experts.' In the end the Conservancy Board were defeated, and the Corporation now pour their effluent unresisted into the river. It may be as well to quote here, as there has lately been question about it, the decision of the judge who tried the case:

'1. I find, first, that so long as the Corporation of Hertford thoroughly and efficiently subject the Hertford sewage to the best practical process of purification they are not liable to an action for discharging the effluent into the river at the authorised place.

'2. I find that the Corporation have treated the sewage, and are still treating it, thoroughly, according to the best practical process.

'3. I find that the accumulation of mud in the Lee below Ware is in no way caused by the Hertford sewage.

'4. I find that no real injury, pollution, or nuisance has been caused by the Corporation to the waters of the Lee.

'It seems to me, therefore, upon those conclusions, that this action ought to be dismissed, and dismissed with costs.'

The clause upon which the Corporation rely for their exemption from the penalties which would otherwise attach to their pollution of the river was originally obtained by them thirty years ago, when sewage disposal was in its infancy; and in the interests of the water companies and the public health it ought clearly to be repealed. To those who

ous of ascertaining in detail the freedom of reaches of the Lee from serious pollution, commend a perusal of a valuable report by Major Flower, printed in the official report of the aminer of the metropolis for the month of . Major Flower goes minutely into the circles of each town on the banks, not only of but also of its tributaries—the Mimram, ine, Quin, Ash, Stort, and Cobbin's Brook ; a mental reservation as to Hertford, he t the conclusion that on the whole the upper s secure from dangerous pollution as could expected in a river so circumstanced.

ut it is far different below the intakes of the companies, and Major Flower himself admits ant animadversions on the state of the river nham and thereabouts are only too true. t is that the enormous increase in the popu- f Tottenham has not been followed by an e increase in the tank-room and appliances sewage works. Hence a large volume of eated sewage passes daily from the works Lee, and besides this there is a frequent e of crude sewage into the dock, which is le the sewage works, and which is 'a seeth- ss of putrefaction.' The Moselle brook, ns through Tottenham, also receives pollu- the population through which it passes. s no need to waste words in describing the affairs at Tottenham. The facts are prac- dmitted on all hands. The water is little han sewage; the banks are covered by : mud, and exhale pestilential odours; boat- bathing have alike been rendered difficult, npossible.

Local Board have been stirred up on the in a number of ways. Under the Act of 1868 referred to, the Local Board of Health have de certain tanks and filter beds, and thereby, best known practicable means, to purify and t the sewage matter passing through the said and, as long as the purification and disin- are effected to the satisfaction of the Con- y Board or the Secretary of State for the Department, nothing in the Act authorises iversity Board to give to the Local Board : requiring them to discontinue the discharge ffluent water remaining after such purifica- o the Lee through the outfall provided for pose.

since 1868 the conservators of the Lee have essing the Local Board on the question, and enlargement; and improvements at the works have taken place. In 1875, the river ery much polluted, the conservators referred utter to the Home Secretary, who gave a in favour of the Local Board. After con- complaints since then, the matter was again l to the Home Secretary, and a public inquiry . Arnold Taylor, of the Local Government was held in January last, following which a f observations and analyses were made. On the Conservancy received the decision, which verse to the Local Board. The notice was last July, and until the expiration of twelve : from that time legal proceedings cannot be y the conservators.

Hackney District Board of Works have also p the cudgels, though their recent memorial Local Government Board is singularly mis-

leading and inaccurate. They begged the Central Board to cause an immediate inquiry to be made, with a view to taking steps for requiring the abatement of the nuisance. This memorial was forwarded for observations to the Tottenham Local Board, and their reply may be taken to contain all they have to say in their own defence. They reply that they are pushing forward the construction of new works at their sewage outfall, which, either alone or with some addition, will certainly, when completed, remove all reasonable ground for complaint, so far as the Tottenham district was concerned. Except after heavy rain, no overflow is allowed to pass into the River Lee. The completion of the new 100 horse-power pumping engine will, the Board are assured, enable them to deal even with the storm water. The Local Board consider that the combined conditions of the reduced flow of water into the river, and the high temperature, which have operated so prejudicially in connection with the sewage outfalls into the Thames during the present summer, must not be left out of consideration in connection with the present state of the River Lee. The experience of twenty years has shown that such results are only possible under such combined adverse conditions, and that they only occur at distant intervals, and prevailed but a short time. The Board have evidence to show that for the past six or seven weeks there has not been sufficient rainfall to require exceptional treatment of the sewage delivered at their works. They are using, and will continue to use, as long as it may be necessary, means for disinfecting and deodorising the dock and the stream passing through it into the River Lee at their sewage works, and have given instructions for the immediate dredging of the dock. Further, they have directed their engineer to prepare and submit a plan and estimate for the construction of a reservoir of sufficient capacity to hold at least a day's volume of sewage preliminary to other works in contemplation.

It is to be hoped that, the matter having now attracted general attention, the Local Board will be kept strictly to their promises, as the present state of the river thereabouts is scandalous to all concerned. But there are other authorities besides Tottenham, such as Walthamstow, Leyton, and West Ham, which discharge their sewage in a more or less purified condition into the Lee, before it reaches the Thames and adds to its foulness. Looking to the growth of these places, and to the strong probability that before long measures will have to be compulsorily adopted for the general purification of the Lee, the plan already designed by Sir Joseph Bazalgette and Major Flower, and Messrs. Law and Chatterton, for an intercepting sewer to take all the sewage of the districts referred to, straight into the Thames below Barking after treatment appears to merit renewed consideration. The scheme seems an ambitious and at first sight an extravagant one; but Major Flower calculates that not more than a sevenpenny rate would be required for the purpose; and that if the expenses saved in pumping and administration of sewage farms be deducted, probably a sixpenny rate would be sufficient. Evidently something must be done, and that without delay.

A PAPER has this advertisement: 'Two sisters want washing.' *Pace* Mr. Edwin Chadwick, thousands of brothers are in the same predicament.

THE PRIMARY PRINCIPLES OF THE SANITARY HOUSE AT THE HEALTH EXHIBITION.

By JOHN F. J. SYKES, B.Sc. (Public Health), M.B.,

Member of Council of the Sanitary Institute.

THE specially selected committee is to be congratulated on the success attending the erection at the International Health Exhibition of two houses, side by side, the one with all its sanitary requirements perfect and the other with all the points of its sanitary armour defective; a suggestion, due to one of its members, Mr. H. H. Collins, which affords an opportunity for the first time of a complete survey of scattered sanitary maxims gathered up and presented as a collective construction.

The numerous appliances in use will doubtless be a source of warning and instruction to householders, and an example to house-builders. But it has been intimated that the approved sanitary appliances which are used are only a few of the many, and these few are not to be considered as of more value than the many of the same class and type. It would therefore be invidious to dwell on them in detail. But if this novel experiment result in definite principles being laid bare to be grasped by those who make our houses, we shall have reached a landing stage in sanitary science long sought for and slowly attained. The methods by which our houses can be rendered obnoxious are so numerous that great credit must be given to the gentlemen who have so ably chosen the typical faults wherewith to build up an insanitary house. Even these are but a tithe of the means employed for inviting dampness, accumulating soakage, collecting dirt, excluding light, preventing ventilation, poisoning the air, polluting the water, laying on sewer gas, and providing other ready means of access to disease. Having no guiding principles they are beyond comprehension, and as for description they are so beautifully contrived and annotated that they must be seen to be appreciated, when they themselves will be sufficiently eloquent in their silence.

In the sanitary house on the other hand we find the corresponding remedies. Dryness provided for by damp-proof courses, concreted basement and ventilation under floors. Cleanliness by the polish and construction of the floorings. Light and air by ample and adjustable windows, each water-closet ventilating independently of the passage by its own full-sized window. Soakage, accumulation and sewer-gas kept at bay by a proper system of draining and ventilation, notably by an iron gas-tight house-drain.

Passing from the points of construction let us endeavour to analyse and grasp as a whole the systems and methods adopted of—

1. Refuse removal.

a. Liquid.

b. Solid.

2. Water supply.

3. Ventilation, warming and lighting.

The drainage comes prominently first, and demands the fullest consideration. It will be most convenient to proceed from below upwards. There being no sewer, the means of sewer ventilation in connection with the house is not illustrated, probably as being still *sub judice*.

The sewer connection terminates in the forecourt by an S trap cutting off air connection with the

house and precincts. The house-drain dis into the S trap through an open conduit run a manhole. To this air is admitted by a tu a grating in the wall of what would be th The long inlet tube, sometimes seen runni high as the roof, to avoid the unpleasant possible reflux of air, is here on good author demned. If the inlet arm of the reversed so to speak, be of the same length as th arm—viz., the soil-pipe, stagnation will result has given rise to a host of mechanical ap for inducing an air current to relieve th nation. We find none of these appliances Provided the manhole is as close to th wall as the inlet here shown, it might be covered with a grating. A goodly number o may be seen with this arrangement worki fectly. Slight deviations in the air curre considerable impediments to its entrance should rather in every way be facilitated. principle remains that the air inlet shoul ground level or as near it as possible. The air of a well-flushed and well-ventilated hou should be scarcely perceptible to the sense: properly constructed back currents sho almost out of the question. That four ir sufficient diameter for an ordinary house- not accepted by all sanitarians, but one p stands out prominently in ventilating drain ever the diameter of the pipes used. The air outlet must always equal or exceed the inlet. If there be two soil-pipes in connecti the drain this is likely to be the case, but not so if there is only one. It is preferable th should be only one, for very obvious reas: this case we have only one and in order t area of inlet and outlet may be equal the drain and soil-pipe are of the same d throughout.

The house-drain and soil-pipe are one cor tube, constituting the only true drain. One horizontal tube of the same diameter thr the joints air and water tight, runs from t court manhole horizontally with an easy a point below where the closets tower on another, and here assuming the vertical d passes without curve or bend to its tern above the roof. Even slight curves or bends impede the air current. There are only tw ings, the inlet at its lowest point in the fi manhole, and the outlet at its highest ab roof. This is a methodical advance; out c sanitarians are gradually condensing defini ciples of drainage. All pipes, from whatever discharging into this vertico-horizontal di water-trapped, so that the air current in i lated. Into the vertical portion or soil-pi pipes carrying excrement discharge, and horizontal portion only branches from the All other pipes, except the excremental ar flow pipes, discharge in the open at ground to the gullies, either directly or indirectly, the rain-water pipes. The rain-water pipes plied with open heads at each floor level, int the waste-pipes of each floor discharge. Pij the safe trays and cistern overflows, wh usually dry, merely project through the wall own floor line into the open air, thus reseml old gargoyles. So that all pipes except th mental are quite independent of the delivery gerous matter or vitiated air. Each waste

ped, not as part of the system, but to prevent ght blowing up, and the safe tray pipes have or the same purpose.

tion must be taken to the housemaid's sink ing into a rain-water head and close to a

The smell of slops is very powerful and nable. It appears that slops are not intended rown down the housemaid's sink, but that to be thrown down the water-closet, the which is hinged and folds back for that

One would suppose that the obvious use k was to receive washings and slops. Wild ould fail to drag the idea from the most nt housemaid, the contrary notwithstanding. re serious objections to throwing slops down osets. The best of drains are liable to e from brushes, flannels, soap-cakes, and neous articles that careless housemaids pour rding an argument in favour of larger-sized an 4-inches. The use of the hinged seat to et would have been more happily demon- on the same floor as the sink instead of on below. Whilst inspecting this water-closet ing incident occurred. I was explaining the f the houses to a distinguished French sanid- lifting up the hinged seat of this closet, d the pan standing up free from the sides in re of the open space, and beneath it the lead a its small pipe discharging through the wall air. There was no tray level with the brim a the spillings of the slops and run them to the pan, and so prevent them from into the lead tray beneath. 'Ah ! que atil,' remarked my French friend ; 'comme lite la supervision. Si la femme de chambre igente en vidant les urines dans le water- u lieu de couler sur le parquet, elles couleront e des passants. Vraiment ! cela facilite beau- olice sanitaire.' That was certainly the view question from the other side of the channel. ; nothing gained by throwing slops down a flushed water-closet, but there is at least against obstruction in throwing them down with the waste-pipe protected by a guard. ve the principle that all excrement dis- g-pipes should deliver into the vertical or s, and, as the housemaid's sink will un- ly become a receptacle for diluted excre- should follow the rule. The housemaid's hould rank as a water-closet. The waste- m it should be trapped, and discharge as pipe of a water-closet. Three water-closets le accommodation for a house this size. most closet space is unoccupied. By re- the housemaid's closet to the topmost floor y above the other closets in the section of e devoted to them, the difficulty is solved at it may be so placed on an intermediate floor.

The basement closet on the same principle might be made to discharge by a shorter connection. With these two trifling amendments, the principles of drainage of the sanitary house can scarcely fail to be grasped as a system by those interested. We notice that there are no wash-out closets. Professor Corfield has pointed out that the reason valve-closets are looked upon with great favour is because by storing a panful of water, and delivering directly downwards on to the trap beneath, they give the greatest power of a full and vertical flush. The overflow-pipe is the opprobrium of the valve-closet. Now that flushing-cisterns are becoming universal, if the overflow-pipe were cut short, the safe beneath (made a little deeper) would become in reality an overflow-tray, and valve-closets might possibly rise in favour. A flushing rim to the pan of every closet is now a *sine quâ non*.

Passing to the solid refuse. Its disposal, removal, and collection scarcely come within the power of the individual householder, but its storage he is obliged to provide for, and the intervals of its collection affect him considerably. With the abatement of smoke, and also the increased use of gas for cooking and heating, house refuse will consist more and more of vegetable and animal refuse and less and less of ashes, entailing a corresponding rapidity of collection and a diminution almost to vanishing point of storage. The daily (possibly nightly) collection of house refuse is 'a consummation devoutly to be wished,' and a measure of acknowledged sanitary importance. It is scarcely likely to be encouraged by the rather large-sized galvanised iron dust-bin without wheels, ironically called portable, although a decidedly improved substitute for its very roomy wooden congener firmly rooted next door. Could a dustman easily manipulate such an iron bin-full ? Would a house this size accumulate this bin-full in a week ? Possibly it might. But certainly not in a day. For the sake of precept a good example might be set to householders and a dust-pail sufficient to hold only one day's dust, or at the very most two in case of mischance, prominently exhibited as the correct thing. Its use, collectively by a large number of householders, would prove that efficient a *posteriori* force which is the only earthly power that can move a corporate body.

The water supply. Firstly we observe that every water-closet is supplied with a flushing cistern preferably of the syphon type invented by Mr. Rogers Field. This provides the happy mean preventing the use not only of too much but also of too little water. But its most important function is to isolate this water from the general supply. Double precautions appear to be taken, for the supply pipes to the flushing cisterns are still further isolated from the dietetic water by having a separate storage cistern specially to themselves. Because draw-off taps are liable to have drinking water taken from them, even when not so intended, they are all supplied from the drinking water cistern. (The placards numbered 41 and 44 have evidently been accidentally interchanged, which is rather confusing.) It is considered politic for each supply pipe from the cisterns to have a stopcock for cutting off the water if necessary. Also for the main-service pipe to have a draining tap for frosty weather. The overflows from the cisterns are merely led into the open air. Altogether the excellent manner in which the storage, distribution, and isolation of the water supply is carried out leaves nothing to be desired.

It is a beautiful example of the intermittent system, but it is perhaps to be regretted that preference should have been given to this system. Even in overgrown London the water companies are adopting the constant supply on a gradually increasing scale. That system is now generally admitted to be infinitely superior. An opportunity presented itself for illustrating what is doubtless the system of the future; for giving some authority upon water meters, the arrangement of pipes, fittings, flushing cisterns, taps, and stopcocks in connection with a system of constant water supply.

Turning to the ventilation, warming, and artificial lighting, we find it less easy to grasp the primary principles involved, due in a measure to the necessities of construction. Let us take the ventilation and warming first, because it is a much simpler matter to supply fresh air to an ordinary dwelling-house if uncomplicated by the requirements of artificial lighting. In summer natural ventilation suffices. In winter or eight months in the year we resort to artificial ventilation. Artificial ventilation may be effected by the extraction of the foul air (vacuum method), or by the introduction of fresh air (plenum method). In both cases in the dwelling-house heat is the motive force. The admitted air may either be cold or warmed. Mr. Ernest Turner says the former is uncomfortable, the latter costly; so that in practice the more nearly the actual supply is graduated to meet the actual needs the better. The Sanitary House has a stove on the ground floor, which introduces warmed fresh air to the passages and staircases. This, which is really a plenum method of air supply, answers a double purpose. It prevents air being sucked into the house from infected sources, and supplies in its stead pure warmed air to the section or shaft of the house devoted to the staircases. For the rooms the ordinary means of ventilation are the windows, doors, and chimney-flues, and during the daytime they amply suffice. The fireplace as the outlet extracts the air (vacuum method), and the windows and doors as inlets admit it. The windows by inter-sash ventilation admitting cold air and the doors admitting warm. There seems to be a great gain in utilising both methods. Warming the admitted air in detail for each room, as by Captain Galton's grates, does not appear to have found favour, or, what is more probable, the demonstration of the working of grates, flues, and chimneys was not found practicable in a structure of this kind.

The extraordinary means of ventilation required during the use of artificial light are provided by longer or shorter tubes and valves as inlets in the outer wall, and longer or shorter tubes over the gas-lights and valves in the chimney breast as outlets. There are three possible methods of treating the ventilation of gas-lights; the first and worst being to take the air supply from and cast the products of combustion back into the room, as seen in the Insanitary House; the second and better being to take the air supply from the inner and cast the products of combustion into the outer air, as seen here in the Sanitary House; the third and best method is to take both the supply from and the products into the outer air, thus isolating the lighting from the air of the house. The favour in which the electric light is held unconsciously asserts this principle. One of the great gains in the use of electricity for private dwellings is that it does not demand special ventilation; because in its hermetically sealed globe (1) it does not foul the air, and therefore requires no in-

creased extraction; and (2) it does not cool air, and therefore requires no increased intake. Wherever it was possible to supply a gas an upcast shaft it should be possible to supply a downcast, and it wants but little more to be completely from the dwelling, without the use of costly special apparatus. Gas would be further assimilated to electricity in reducing from fire to a minimum, and avoiding the draughts caused by unequal draughts. Lighting the room would be an impossibility without the isolation of the gas-lighting system complete as that of the drainage system. The introduction of electricity points out this principle.

In conclusion, this goodly sized model with most important indications for house ventilation without placing any particular system in relief. For those who construct our dwellings seek primary principles to guide them, this paper may facilitate their endeavours to get out from amongst the numerous sanitary a-

SMOKE CONSUMING LOCOMOTIVES.—In a paper read at the meeting of the British Association for the Advancement of Science at Montreal, by Mr. J. Bar, an anthracite burning locomotive, the statement on the authority of the Reading Railroad at Plattsburgh, large users of anthracite, that 1 lb. of anthracite produces 6 lb. of water; 1 lb. bituminous coal, 7 lb. of steam, under similar conditions. Comparing the cost, and the economic efficiency of 75 per cent., bituminous coal, 75 per cent. The Pennsylvania Railroad reports that to be 25 per cent. the more costly fuel. It described the locomotive for burning anthracite, the advantage being the small amount of dirt, free from smoke, and cleanliness, which it is highly favourable for passenger service. It is not used by any of the anthracite mines.—An engine of a new type has recently been constructed by the Brooks Works for the Chicago Locomotive Iron Company. The head-light is placed where generally it is, while the stack at the rear of the boiler and close to the cab. The boiler is one of the latest manufactured (what is known as a 60 ft. boiler) and the smoke, gas, &c., traverse it twice, bottom and over the back on the top to the smokestack. This makes such a good combustion that the fuel, the gas, and the smoke are almost completely consumed, and when the engine is going at full speed it is impossible to see any smoke. The smoke is very small, being not more than 7 in. to 8 in. in diameter. The patentee, Mr. Charles B. Coventry, claims the advantages of this invention that it gets a strong draught, reduces the waste of fuel to a minimum, throws no cinders, sparks, or fire. The locomotive is peculiar in appearance, but it is said that it does well. It weighs 40 tons.

THE COLLECTION OF REFUSE.—The Viennese have recently adopted a new method of refuse collection, based on the assumption that infection is not unfrequently mixed with dust, sweeping, and that by transporting such rubbish on open carts there is at least a possibility of disease being disseminated along the route of conveyance. It consists in having all refuse put into barrels with tightly-fitting heads. These barrels are then carted away to the proper locality, emptied, and then returned. In order that every house-keeper keep his own, the name and address of the owner is painted on each barrel. The Vienna authorities are making a valuable experiment, and if it proves successful and not too expensive, it may be hoped that other cities will not be long in following so good an

IMPROVED DWELLINGS FOR THE WORKING CLASSES AS SHOWN AT THE HEALTH EXHIBITION.

By JOHN PRICE.

CONSIDERING the great outcry we have heard of late respecting the housing of the poor in London and other large towns, it might be naturally expected, that we should find in the Exhibition, the details of comprehensive and practical plans for dealing with this important question; but a somewhat careful examination of the various models and plans exhibited, leads us to the regretful conclusion, that little real progress has been made towards a satisfactory solution of the great problem of the day.

Several excellent models and plans of improved dwellings are shown, but the majority of them are attended with a common drawback—the very excellence and costliness of their arrangements and fittings prohibits their use by the real labouring poor, by reason of the improved rents which are necessarily demanded to make such dwellings fairly remunerative. The poor coster, the dock labourer, and the immense army composed of other poor people always to be found in London, who cannot boast of any regular income, and who literally live from hand to mouth—these find it utterly impossible out of their limited resources to pay the rents asked for accommodation in those palatial residences which have lately sprung up so rapidly in almost every district of the metropolis; they are thus compelled to 'move on,' and give place to their better paid and more fortunate brethren.

The plea urged by the promoters of these new blocks of dwellings, is that although they do not profess to provide accommodation for the very poor, that class is indirectly benefited, as the old houses vacated by the tenants of these new blocks are thus thrown open to them. These vacated dwellings as a rule will be found in some degree superior to the lowest slums, which were perhaps previously the limit of the choice of the residuum.

Unfortunately this view of the case is not universally accepted by those most affected by the building of these huge blocks on the site of their old homes, who complain sadly of being thus evicted, and obtaining no satisfactory compensation. It is not my intention, however, to enter into any dissertation on this phase of the question, but merely refer to it *en passant* as one which is frequently encountered by those who come in daily contact with the poor. It is a much more agreeable task to glance briefly at the various models and plans exhibited.

The premier place must be awarded to the Improved Industrial Dwellings Company, whose plans, elevations, and models of buildings form a conspicuous feature in Class 32 (main entrance). This company has for the past twenty-one years devoted more capital and perhaps exercised a greater influence in this direction in London than any other agency. The company now possess thirty-one blocks of tenanted dwellings in various parts of the metropolis, some of large extent. They have also four other sets in course of erection. When these are finished they will have provided accommodation for a total population of about 25,000 souls. The various blocks of the company are pretty well known landmarks to the residents of London, and it is unnecessary to refer to them separately, but will

rather confine our remarks to the extensive blocks at Soho, formally opened by the Prince of Wales on July 8, but not yet quite finished, as embodying all the improvements suggested during the long practical experience of the company. (See SANITARY RECORD for Aug. 15, vol. xv. p. 78.) A glance at the plans of the two blocks shows that not only the company, but also their tenants, will profit largely by such experience. The improvements over the old blocks consist mainly in an increased size of the rooms, with a better arrangement for allowing a perfect current through, thus securing good ventilation without the aid of mechanical contrivances, except that the fanlight to be found over every door can be opened or closed as desired. Another improvement in the front elevation is the absence of the balconies giving access to the dwellings on each storey—which in this case have been judiciously removed to the rear—the front of the Sandringham Buildings, therefore, present the appearance of ordinary houses, and this symmetrical if not ornate design, will be a credit to the new street, as well as to the architect. It has always been a cardinal feature in this company's arrangements that each dwelling be essentially self-contained and that the tenant should not have to go outside his own door for any convenience. It must be admitted that in some of the older blocks of the company this advantage has only been obtained by the sacrifice of other equally desirable features—viz., the complete isolation of the water-closet and sinks from the living rooms and unrestricted light and ventilation. In the newly-erected Sandringham Buildings, no valid complaint can be made on this score. The water-closets are well separated from all the rooms, and placed against the exterior wall, and ventilated by a good window. Another noticeable improvement is the dust shafts, which are now so contrived and placed as to give the tenants no inconvenience. One of the most pleasing features of the arrangements is the liberal allowance of playground for children—a necessary adjunct to buildings of this description, but not always met with where land is of such value. Taking all things together, the company may be congratulated on the success they have achieved, and, considering that they will probably derive a handsome revenue from the forty-four shops on the ground floor, let us hope that they will be able to accommodate some portion of the late inhabitants of the site. The company being their own builders, have a guarantee that the work is carried out in integrity. They also exhibit specimens of sanitary and domestic appliances and materials used in their buildings, which are all of good quality.

One of the most attractive elevations of artisans' dwellings shown in the Exhibition are those designed by Mr. E. Hoole for the Lambeth Dwellings Company, in the Lambeth and Kennington Roads, which were erected at a cost of about 20,000*l*. Some people may possibly object to the Gothic design of this block; but it is certainly preferable to the repulsive, barrack-like appearance of those early blocks of dwellings which provoked the antagonism of those for whom they were erected. Here again we find the ground-floor utilised for shops, which must materially assist the revenue. The sanitary conveniences are placed outside the dwellings ranged in a well-ventilated corridor, so that there is little fear of any effluvia reaching the tenants from that source. The block has a sound and substantial look about it, being the

product of a gentleman who has devoted considerable study to the requirements of the working-classes. (*Vide* SANITARY RECORD, April 15). I believe the company are content with a less dividend than 5 per cent. for the excellent accommodation they offer.

The National Model Dwellings Co. of 49 Cannon Street, E.C., exhibit plans and elevations of the large blocks of dwellings they have acquired, and which are situated on the site of the old Queen's Bench Prison in Southwark; these are six stories high, have a good appearance, and from their eligible situation (being close to the Borough Road Railway Station) they always command good tenants; again we find the ground floor appropriated to shops; the arrangements do not call for any particular comment.

Mr. James Webster, of Doughty Street, exhibits the plans, &c., of a small block of improved dwellings, erected in Whitechapel for A. L. Dussek, Esq., which, for convenience of arrangement and quality of material and workmanship employed, are second to none, the proprietor being probably actuated with the idea that where everything is of the best, repairs will be less needed. In London there are always to be found a sufficient number of well-paid artisans, able and willing to pay for superior accommodation. The block is only four stories high, with laundry and drying-ground on the roof. The dwellings are fitted with dressers and cupboards nicely painted, as well as other conveniences which are doubtless appreciated by those who can afford to pay for them.

Mr. Edward Clarke, of 6 Adam Street, Adelphi, exhibits drawings of blocks of industrial dwellings, erected in different parts of London, which do not show any original designs. The Corporation of Liverpool is one of the few municipal bodies in the kingdom who have had the courage to take the bull by the horns in grappling with the difficulty which has dismayed less energetic bodies. The plans exhibited of the extensive blocks of dwellings now being erected at Nash Grove for that Corporation, are a splendid testimonial of their determination to do their duty, and should incite other Corporations to follow their example. (*See* SANITARY RECORD for March 15, vol. xv. p. 437.) There is no doubt that Liverpool is much indebted to Mr. A. B. Forwood, Chairman of the Insanitary Committee of the City Council, for carrying out this laudable design to a successful issue. Mr. Forwood has long taken deep interest in the important question of housing the poor, and his contributions to the literature on the subject are much valued. His description of the thirteen blocks now being erected at Nash Grove will be found on page 291, vol. xv. of the SANITARY RECORD, together with a mass of other interesting information. Drawbacks to the success of blocks of dwellings are met with in the provinces which are rarely encountered in London; they cannot be gauged by a common standard, and are much affected by local influences.

The Oddfellows' Co-operative Building and Investment Co., of Manchester, exhibit plans and photographs of houses which have been built and purchased by thrifty workmen, through the aid of the Company; they are admirably designed, and visibly teach us the benefits of self-help. The other drawings, &c., of improved dwellings in the Exhibition, though of much merit, present no peculiar features needing any detailed description.

EVEN delirium-tremens is now traced by German physiologists to a micrococcus—'the worm of the still.'

THE SANITARY RECORD SEPTEMBER 15, 1884.

The Editor will be glad to receive, with a publication, announcements of meetings, & proceedings, and abstracts or originals of, read before the members of any sanitary or association.

THE THAMES VALLEY DRAIN

BOTH the rivers that supply the metropolis drinking water have lately come in for much indignation, and a good deal of somewhat writing has gone on as to the sewage pollution which they are exposed, and the dangers public health likely to arise in consequence. The Thames nor the Lee is an ideal source of potable water; but it is necessary in fairness to set out exactly the state of affairs with regard to the river, in order to see how far the recent about their insanitary conditions justifies as to the safety of the water which their upper supply. The case of the Lee is fully set out in a separate article on page 92; and may be advantageously explained to those acquainted with the Thames the relations of admitted pollution of that river to the question of the purity of its water as a beverage, in order to prepare the mind for an accurate survey of the present position of the drainage of the Lower Valley.

In order to understand the position of the pollution question, it is necessary to supply the River Thames divided into three districts: first, and the most important as regards the water supply, extends from Cricklade to the source of the London water supply near Hampton. The a trifling discharge of sewage at Henley not remedied, and part of the sewage at Staines flows into the river. Against this local source of pollution three convictions have been obtained by the Local Board of Conservators, and, in consequence, the evil is to be remedied. With these two not very important exceptions, the whole of the sewage from the towns and smaller places above the London water supply has been diverted from the river. The next district, passing down the river, from the sources of the London water supply near Farnham to the limit of the metropolitan area below Chiswick, sewage from all the towns, except Twickenham, still passes into the river. The third district, from Chiswick to the Metropolitan Board of Sewage Outfalls at Barking and Crossness, sewage is exempted from the operation of the Metropolitan Board of Sewerage Acts, and the sewage works are under the control of the Metropolitan Board of Waterworks. The Royal Commission is still inquiring into the pollution of the river by these sewage works, and dealing with the bulk of the sewage of the metropolis.

the second of these districts that we propose direct attention.

tory of the Thames Valley drainage is a very able proof of the difficulty of carrying out in the way of remedy for river pollution. In a good many years since a Royal Commission was ordered by the Duke of Richmond, the Thames as a sufficient and proper water for the metropolis, provided it could be kept sewage. The Metropolitan Board of Works was obliged to do this as regards London, and splendid main-drainage scheme it has done so extent of intercepting the sewage from both of the river, and carrying the outfall some own. The quantity, however, has of late increased so much that a good deal comes up at tide, and the point of outfall will ultimately have to be carried a great deal down, or, if possible, kept out of the river. Hence, the intake of the London water companies has been successively moved up from Rotherhithe, Lambeth, Chelsea, to Seething and West Moulsey. The main-drainage had materially improved the quality of the water at the lower intakes, but it became manifestly necessary to prevent sewage from getting into the water from the populations fast aggregating on the banks above the scope of these works.

the towns from Lechlade to Putney, a stretch of miles, had, by the Acts then in force, been ordered, at great cost, to establish sewage systems discharging into the Thames. But when the Duke of Devon's Committee reported in favour of taking London water supply from the Thames, London

Act passed compelling all these places to spend more money in undoing what the previous Acts had compelled them to do. The worst of it was that while they were compelled, under heavy penalties, to prevent any sewage from reaching the river, they were not told how else to dispose of it. In fact, no other mode was pointed out, and none was known, and so, while the Act of 1867 with 100*l.* a day of penalty on offenders, up till now the sewage of the riverine flows into the river pretty much as it did in 1867, and in increased quantity. Yet the Acts have made persistent and energetic attempts to obey the law, but unfortunately the Act imposed the penalty did not give the necessary means for acquiring land, or for constructing works necessary to dispose of their sewage. Kingston, Hampton, Barnes, Mortlake, Kew, Esher, and Isleworth have successively made attempts, singly or jointly, some of them several but so far have met with nothing but failure, by interested parties, or by proprietors convinced that such works anywhere within a radius of two miles would damage their property.

these places are now at the mercy of London, and can at any time proceed for penalties, and have been so. It did so and recovered them from London, and though that town got a special Act some years of grace free from penalties, those have expired, while no scheme has been found yet, and the sewage still runs to the river. London Wick was proceeded against, and penalties of 98,000*l.* were claimed. The rateable value of London Wick being 11,000*l.* a year, such penalties would soon have swamped the fee-simple of the parish. This violent action, however, led to the formation of a Joint Board, to include all between

Hampton and London, with the exception of Brentford and Twickenham. All the localities were relieved of their penalties and of their obligations as to sewage, and three years from 1877 were allowed to the Joint Board to carry out the work. The Joint Board set about their task energetically; they got plans from the most eminent engineers, and after full consideration adopted the best, and set about carrying it out; but on considering their powers they found themselves at fault. They required several crossings of the river, and the House of Lords had decided that while the right to acquire lands for their purposes could be got by Provisional Order, water rights or power to make works in the river channel could not. One plan after another had to be discarded, and when they tried for an Act of Parliament they were defeated. They then fell back on a scheme for lands at Mortlake, where the sewage was to be precipitated, and the sludge, heretofore the trouble in all precipitation schemes, was to be dealt with by pressure and reduced to practicable shape. They got a Provisional Order from the Local Government Board this year, but it had to lie before Parliament for forty days for ratification, and before these had expired the House of Lords, moved by interested objectors, threw it out, and so matters remain as they were before.

Thus we see that local authorities most anxious to do their duty, and spending much money to do it, were baffled singly or in small combinations for ten years, and when at last a Joint Board was established, and three years more were allowed for the work, the same baffling process has gone on for no less than seven years, and the sewage runs into the Thames as before, nothing having been accomplished except the expenditure of some 28,000*l.* of the ratepayers' money; while the Joint Board is now, and has been for about four years, in the position of 'a local authority that has made default in providing its district with sufficient sewers,' and its whole district is liable to heavy penalties.

In the recently issued Report of the Commissioner of the Metropolitan Police for the year 1883, particulars are given of the operations of the police for the enforcement of the Smoke Nuisance Abatement Acts, from which it appears that—as noted in the *SANITARY RECORD* of June 16, Vol. xv., page 591—two-thirds of the offences against the Acts were punished by fines below the minimum of 40*s.* 'In steam boiler furnaces of the ordinary type very little advance has been made in reducing smoke. Mechanically stoked and certain other special furnaces, though efficient for preventing smoke, are inapplicable in the great majority of existing London works. In numerous instances the incompetency of the stoker is the cause of smoke, and it must be added that employers, in the absence of any system of certificates of competency, are at some disadvantage in securing qualified stokers. In restaurants, hotels, &c., the heating and cooking apparatus used has, in many instances, been very considerably and beneficially modified within the period under consideration. The use of gas and coke for heating purposes has also much extended, and in that proportion the smoke has been diminished. A very large quantity of smoke, which is preventable, however, still issues from these establishments, which are increasing fast, in size and number, in almost all districts. Smoke is still being produced by the potteries of the metropolis, and proceedings are, after the necessary cautions, taken against the stokers or proprietors as may be necessary. Until improved systems of furnace are adopted, such as are successfully in use in some parts of the kingdom, the smoke from these sources is not likely to be reduced.'

ALCOHOLIC DRINKS.

A RECENT voluminous and able article in the *Times* on alcoholic drinks, with the correspondence and a somewhat apologetic leading article which followed, have drawn considerable renewed attention to the burning question of alcohol. Most of the correspondents of the leading journal were indignant at the assertion that teetotal societies 'do very little good, and a great deal of harm,' and at the contention that teetotal advocacy is the wrong way to go to work to cure drunkards. Few unprejudiced persons will deny that the writer of the first article here went entirely out of his way to cast an unmerited reproach on an agency which, after every allowance for its failures, has accomplished a wonderful work in the permanent reformation of a very large number of pronounced inebriates. Alive to this false step, the *Times*, in a sympathetic leading article, returned to the subject, and frankly admitted that the drink question as a whole involves wider issues than mere individual gratification; the design of the original article having been of a more limited character—viz., whether temperance or total abstinence is the more healthful and helpful to the average members of society.

In the course of his argument the writer in the *Times* evinces on the one hand considerable insight into the physical development of inebriety, and, on the other, falls into several errors which it may be well to point out.

He fully recognises, what many abstainers have not yet seen, the existence of a class of inebriates labouring under 'a manifest disease,' constant or intermittent, but uncontrollable during the paroxysm. For these the proper remedy is restraint or seclusion in a home for inebriates, freed from all temptation to drinking. He also rightly calls attention to the defective character of the usual temperance rescue work, in so far as that does not attempt to deal with the causes of inebriety in the individual. If temperance reformers would study the proceedings of the Society for the Study and Cure of Inebriety they would acquire a knowledge of the predisposing causes of the indulgence of their converts, and thus be in a position to arm these latter with weapons capable of resisting their innate foe, or, still better, be enabled to so restore sound health of body and mind as to prevent a fresh outbreak. The writer hits, too, a blot in the teetotal propaganda. Excitement is not strength, nor enthusiasm permanence; and reliance either on these, or on the wearing of ribands by the habitual drunkard, is inadvisable and unsafe.

With much common-sense the *Times* mingles many fallacies, the approving production of which in the present day amounts to an anachronism. It is claimed that excessive drinking is not so much a cause of crime as the outcome of a criminal propensity. This is in accordance with the view that all inebriety has a physical origin, and that the inebriate is only exhibiting the symptoms of disease in his drunken eccentricities; but is not the view commonly held. With no desire to undervalue the disease aspect of inebriety, we fail to see how a murder committed in the fury of drunken madness by a man who, when unaffected by drink, has been incapable of such of crime, and who was utterly unconscious of having killed anyone, can be credited to anything but alcohol. One might with equal propriety declare that the dislocation of a shoulder-

joint from inability to stand on one's fee drunken fit arises not from drinking, but from locating propensity. The judges, therefore, are in attributing a large proportion of crime to temperance, and (as Mr. Justice Hawkins Lincoln the other day) the absence of serious to the cessation of drinking. There is, however, a grain of truth in the writer's argument: then times a criminal propensity waiting only in relaxation by some narcotic to assert itself overt act of horror. In such cases the man must clearly be credited with the deed.

The *Times* contends that alcohol supplies and is a valuable food. There are states of health where no other substance can be resorted to and where as a medicinal remedy the very amount of nutriment in an intoxicant, being administered in a form which can be utilised in the tides the exhausted patient over the crisis; ordinary health alcoholic drink cannot be classed as a valuable or a safe food. On the contrary, it reduces muscular power and exhausts force. Taking into account all the saccharine and nutritive constituents in the most nourishing alcoholic drinks, so minute are their nourishing properties that one would become intoxicated and over again before coming within hailing distance of a scanty meal. Practically, alcohol is not a food, and certainly not a bland innocent food, strictly in a physiological sense.

The *Times* has fallen into a curious mistake supposing that the total abstainers have taken the wearing of a blue riband. The truth is that a minority of water drinkers have donned this, and many flaunt it who are in the habit of drinking intoxicants. It is also open to question whether the statement is accurate that the bulk of the teetotalists are sickly and feeble in appearance.

It is difficult to understand how so able a journal could possibly recommend gin as the purest and best form of spirit. It certainly cannot commend its usefulness, when spirits are called for on therapeutic grounds, with whisky or brandy, unless for medicinal purposes. The less said about its purity the better.

There can be little doubt that there are persons

Rari nantes in gurgite vasto,

whose health is improved by a restricted allowance of some mild stimulant, but for the great majority of men and women the writer's dictum that moderate drinking is more healthful than total abstinence is opposed to the evidence of accumulated experience and indeed crucial tests. Insurance companies find it to their advantage to accept a lower premium from abstainers than from non-abstainers, because the rate of mortality is lower among the former than among the latter: while the records of sick clubs show that inability to work from disease exists in a proportionately greater amount among the members who are not teetotalers. The adult in ordinary health alcohol is not a hindrance but a hinderer of work. So with happiness. Alcohol blunts the senses, and lessens our capacity for pleasure. Other conditions being equal, the abstainer has a much keener enjoyment of life than either the moderate or immoderate drinker.

The writer is in error in the belief that the total abstainers are of a commonplace kind. The labour of both abstainers and non-abstainers may be mediocre, but some of the best work, physical and mental, which the world has seen has

l on total abstinence. Weston recently ppendous task, never before attempted, holic stimulants, delivering a witty, ture at the close of each day's walk of for four months consecutively. ussian factory law imposes the following the employment of children :—1. Children rom ten to twelve years are only permitted g the day in certain specified industries. rom twelve to fifteen years are to be allowed ork in spinning and textile factories, as well orks. 3. Work is formally forbidden to r fifteen years in the following branches of r others, in mills where lamb's wool, felt, and down are worked up; in bleaching ashing, bleaching, and dyeing; in cloth lling, teaselling, and shearing machines; in dyeing works; in all unhealthy work in ain and parchment works, except in some ents; in varnishing leather, in grinding onic and turpentine products; in potteries ks—for the preparation of material, turning, lishing and baking (moulding is authorised); re lime and alabaster are fired.

SULPHUR AS A DISINFECTANT.

It is to be feared that in estimating the value of various modes of disinfection enough attention has not been paid to the difference between deodorants and disinfectants. If by the latter we mean agents capable of destroying the danger arising from infection of whatever kind, we may assert with confidence that they are few in number as compared with the former. Russian leather might fairly be called a deodorant, but it is certainly not a disinfectant. Indeed, we are inclined to suspect that, in the search for new and so-called scientific methods, too little attention has been paid to a method older than them all, the thorough and repeated use of the scrubbing-brush and soap and water; too often the masking of one stink by another has been all that has been attempted.

The burning of sulphur is one of the oldest methods of disinfection, and still remains one of the best. The room to be disinfected should previously be well scrubbed with soap and water; not merely for the sake of cleanliness, but also because it is found that the action of the sulphur is facilitated by moisture; if two strips of blue litmus paper, one moistened and the other dry, be placed in a vessel with burning sulphur, the moistened strip will be found to be reddened more quickly than the dry one. All the windows, doors, and ventilating apertures should be closed before the sulphur is ignited, and not be opened for four-and-twenty hours. A convenient mode of burning sulphur in a large apartment, such as a hospital ward, is by means of a workman's devil—i.e. a bucket with perforated sides and bottom. This is filled with shavings and coke or coal, and, owing to the thorough draught, soon gives a good fire. The sulphur is put with the coals, and a large kettle placed on the top of the 'devil,' by which means steam is diffused through the air and the requisite moisture obtained. A few saucepans containing sulphur, and, if wished, a little methylated spirit, may also be placed in different parts of the room. Seven pounds of sulphur will suffice for a large ward. By some the quantity required is reckoned at half an ounce for every ten cubic feet of space.

For ordinary rooms a gas stove may with a little ingenuity be so arranged as to burn the sulphur and keep a kettle steaming at the same time. If some such device be not adopted, a practical difficulty is often found in keeping the sulphur alight. (*See p. 118.*)

In the process of burning the sulphur unites with the oxygen of the air to form sulphur dioxide, which is easily recognised by its acrid odour. This sulphur dioxide or sulphurous acid combines with free ammonia, and also decomposes any hydrogen sulphide present in the air; it thus acts as a valuable deodorant; it has been supposed to act powerfully upon organic matter, especially in the absence of free ammonia; it has also been stated to completely disinfect miasmata. It is said that the hypothetical bacteria of disease are more easily destroyed than the ordinary bacteria of decomposition; but De Chaumont and others have found that 'disinfectants' required to be used in poisonous quantity before they affected low forms of life such as bacteria. Moreover, some disinfectants, as potassium permanganate, have little action on bacteria, whilst alcohol prevents the development of these organisms but is no disinfectant.

NOTES OF THE MONTH.

ISLE OF WIGHT SANATORIUM.

A NEW health-resort has just been opened at Blackgang, in the Isle of Wight, which seems calculated to supply a long-felt want. The establishment consists of a mansion with out-houses erected upon an estate of some forty acres. The property, which was formerly known as Southlands, belonged to the late Rev. E. B. Puzey, D.D. It was transferred in April to its present occupiers, who have since kept numbers of workmen employed upon it, in order to adapt it for its future purpose. It will at present accommodate about twenty inmates; but with the addition of other premises which are shortly to be built, between sixty and seventy persons will be able to be received. It is intended for invalids requiring change of air and scene, who object to the monotony of ordinary seaside lodgings with their small variety in diet, and to hotels with their attendant excitement and irregularities of all kinds, which are so unsuited to the convalescent or to the fatigued and dyspeptic dweller in towns. But if the sanatorium is not an ordinary hotel, neither, on the other hand, is it a hydropathic establishment; it is to combine the advantages of the two, and to be conducted in such a manner as to make it a suitable site for those who desire a quick return to health and strength. Rest and fresh sea-breezes, with the surroundings of splendid coast-scenery, will be at all times obtainable, and those by whom such adjuncts to convalescence are required should here be able to satisfy completely their very natural longings.

The sanatorium, being situated between six and seven miles from Ventnor, is approached from London by train to Portsmouth, thence by steamer to Ryde, by train again to Ventnor, and finally by coach to the destination. The train leaving Waterloo Station at 11.35 A.M. seems well suited to the would-be traveller; as it lands him at Blackgang at about 5 P.M., and allows him to take a luncheon at Ryde Pier Head, after the arrival of the boat from Portsmouth and before the departure of the train for Ventnor. The route from Ventnor follows the well-known road through the Undercliff by Steephill Castle, the Royal National Hospital for Consumption, and St. Catherine's Point. At this stage of the journey, on a fine day, the southern coast of the Wight is seen ahead to the west, trending away to Freshwater Bay and the Needles; on the right hand is the high cliff extending to St. Catherine's Down; while to the left, between the roadway and the sea, nestles the sanatorium. From this description it will be obvious that the locality is thoroughly protected by the uplands from all northerly and easterly winds; at the same time it is open to the south and to the sea.

The roadway conducts one down the cliff to the lawn and the house, which are situated on a plateau about 150 feet above the shore. The residence has been fitted with all the newest sanitary appliances, including the ventilation of soil-pipes, Tobin's airshafts in the bedrooms, the best flushing system in the water-closets, a Jennings' bath, electric bells, and a liberal use of asbestos non-inflammable paint over all woodwork employed in the building. The amusement of the inmates has been liberally provided for, there being a billiard-room, lawn tennis and croquet ground, bowling green, archery ground, and other sources of recreation on the property

itself, whilst the adjoining cliffs, shore, and can be utilised for most varied walks and excursions of all kinds. There is close to the ground widely-known Sandrock aluminous chalybeate to which the inmates of the sanatorium will free access at all times. The general water of the establishment is irreproachable, and as a spring from the cliff far from all fear of contamination whatsoever. There is a good garden well stocked with vegetables, and the grounds are generally bright with flower beds and many bright evergreen and other shrubs. The kitchen department, it is promised, shall be well attended to, and altogether the establishment seems likely to prove highly restorative to those who seek relief of strength and vigour within its walls. Their honorary medical council, which includes thirty medical practitioners, metropolitan and provincial. The terms seem to be moderate, and inclusive, so that the cost of residence can be exactly reckoned beforehand. Mr. Anthony Brook, of 20 St. Helen's Place, London, E.C., managing director, and will gladly furnish a particulars that may be required.

THE NEXT EXHIBITION.

ALTHOUGH the Health Exhibition has not been full working order until nearly half its allotted time has expired, preparations for its successor are now being made. During the coming year we are to have an International display of Inventions and Musical Instruments. Upon the latter the SANITARY RECORD will not have much to say, but sanitary science has recently been such a wide field for inventive activity that we must be prepared to meet old friends with slightly altered faces, although the Executive Commission wish to exclude such exhibits as have already appeared in the present Exhibition, or its forerunners the 'Smoke Abatement' and the 'Fisheries' exhibitions. Exceptional circumstances will of course be pleaded in behalf of many who wish to contribute, and it is difficult to see how exhibitors can do otherwise than prove a good case. There seems to be no lack of the comprehensiveness of the prospectus, and the group is adequately represented (as desired by the council) only by recent inventions or improvements. There should be no vacant space. Workshops, mines, sanitary appliances, as might be expected, are again included; in fact, every branch of the present show seems represented, apparent the addition of all the direct and indirect applications of science to manufacture or production. Food, agriculture, science and singing, are still to find a place, and such general interest having already been brought to bear upon similar details, it can scarcely be doubted that if such be continued the exhibition at South Kensington will not be sufficiently large for these purposes.

SANITATION AT BRIGHTON.

THERE is no doubt that families run great risk of illness from the insanitary condition of the tenements occupied during the usual summer holidays, and were it not for the out-door life they lead under the circumstances, and the ever open window doors to dilute the inner atmosphere of the tenements, we should hear of more cases of serious illness now brought to notice. It is no exaggeration to say that in many of the smaller seaside

the houses comply with the ordinary sanitary wants of common sense, and it is only in cases in the larger towns that anything satisfactory state as regards individual can be pointed to. An example on a very scale of 'sanitary houses' is exemplified at righton, where a number of high-class flats have been completed by the building owner, in T. Chappell, of Lupus Street, Pimlico. A invitation was issued to those interested, and a body of architects and sanitarians assembled to inspect the provisions made in this respect. All modern and accepted theories as regards subsoil drainage were shown in working order, and their points that would not be required in any house were wanted and put in practice here. Considering that these are flats or houses one or the other, it becomes evident that the drainage of houses has to be arranged for in a limited way and the way in which these requirements have been formed the occasion for congratulation on the part of the experts present. A special feature of the construction of a large pipe-chamber in which all the different pipes are placed, and from which all the different floor levels they enter the separate pipes. No pipes, therefore, enter a residence, except those which belong to it. A lead lined pipe is also provided along the course of the pipes in the flat, and as this discharges into the pipe-chamber, no leakage in any one flat can inconvenience the residents of another. A permanent inspection is placed in this pipe-chamber by which the owner can ascend. Where the soil-pipes enter the flat, a screw-off inspection cap allows them to be cleaned out when necessary. The soil-pipes are of cast iron, flanged and socket-jointed, and open at the top above the roof. They are led into a pit from which the main drain runs away; just before entering this pit the soil-pipes are syphon-trapped, the pit itself being ventilated by a pipe to the roof. Half-way between the soil-pipe and the pipe-chamber above described, an air shaft is provided, from which a current of air passes through the soil-pipes; it has been proved to be the case by repeated tests. The various other points are attended to in the principles laid down for the 'Sanitary House' at the Health Exhibition, and it speaks for itself that the movement that property of this kind has been carried on in this style without regard to cost, the one idea being consistently kept in mind that a better way is necessary to make it complete is included. When we see building owners looking to the front like this, we realise the great progress that are being steadily made in this line.

DETERMINATIONS BY SANITARY AUTHORITIES TO SUPPLY WATER.

Reading daily journal reports a decision of the Government Board which it somewhat erroneously regards as of considerable importance to sanitaries throughout the country, though, as a matter of fact, it is of a very elementary kind. The chairman and members of the Milton-next-Sittingbourne Sanitary Authority were recently surcharged by the district auditor to the amount of between 30% of the sum they had, by resolution, set aside as an abatement to certain brick manufacturers on account of water supply. This company

own all the cottages in the parish of Murston, near Sittingbourne, and the sanitary authority, in consideration of their taking the water for each dwelling, and themselves paying for the whole, agreed to supply them with water from the public mains at an abatement of 25 per cent. from the general scale of charges. The reasons stated by the auditor for the surcharge were that 'the abatement was made in contravention of the order of the Local Government Board, dated June 24, 1881, which fixes the scale of charges for water supply in the parish of Murston.' The Local Government Board, however, have very properly expressed their opinion that 'the auditor's reasons are not applicable to the facts of the case,' which was not a case in which steps were taken under sect. 22 of the Public Health Act to enforce a supply of water. That being so, the scale did not apply, and the authority were at liberty, under sect. 56, to enter into an agreement for supplying water on such terms as might be agreed upon between them and the persons receiving the supply. Under these circumstances, the Local Government Board considered that there had been no contravention of the order by the authority, and they, therefore, reversed the surcharge. Obviously this was the only course open to them. Auditors' auditing would become as great a bye-word as Justices' justice if ignorant straw-splitting of this kind were not officially frowned down.

WHOLESALE ADULTERATION.

ADULTERATION, like legitimate trade, of which it has been described as a particular form, has a wholesale and a retail aspect. The latter is rightly relegated to the analysts of the local authorities, and it would seem natural that the former should be controlled by those attached to the central authorities or departments through whose portals the goods in question must pass before being dispersed over the country. In some cases these would be the sanitary authorities of sea-port towns; in others, the analysts of Somerset House. It is monstrous that while the petty grocer is punished for selling adulterated goods of the nature of which he is ignorant, or as to which he has failed to satisfy himself, the same should be openly sold in the city, the auctioneers and buyers alike well knowing them to be unfit for food. Little is to be hoped from Somerset House, for no man can serve two masters; and, while exercising a vigilant control over all that affects the excise, the officials there seem ready to condone adulterations that do not, though why the special clauses of the Sale of Food, &c., Act relative to tea should not be extended to all articles of consumption we cannot imagine. But pending such amendment of the existing law, it appears to us unpardonable that the sanitary authority of the City should not interfere with the sale of adulterated goods in public auction, and by a single act save the country at large from being inundated with worthless or unwholesome articles. From time to time Messrs. W. and D. Harvest, as self-constituted inspectors of the pepper market, have reported in the papers, after ineffectual protests on the spot, for which they have been soundly abused, the sale of dirt and rubbish under the name of pepper dust or P.D., and now they report the sale of not less than 240,000 lbs. of pepper, the salvage from the recent fire at New Crane Wharf, saturated with water pumped from the Thames, which we know to be there at least little better than dilute

sewage. We heartily agree with Messrs. Harvest that when a competent judge of such things gives it as his opinion that any goods whatever are of an unwholesome or grossly inferior quality, the sale should be stopped by the City authorities pending an analysis, and that if these suspicions be confirmed by the analyst's report, they should then be condemned and destroyed. Once sold these goods are rapidly dispersed and can no longer be traced, and more good would be effected by one such seizure than by hundreds of raids upon small shopkeepers. The great sinners would be adequately punished and much irritation and seeming hardship incident to the application of the Act to the retail dealers avoided.

THE INSPECTION OF CANAL BOATS.

THE studied neglect of the claims to the Government Inspectorship of Canal Boats, created by the Act of this session, of Mr. George Smith, of Coalville—to give him the agnomen of his own choice—has been received by the press with universal dissatisfaction. But, for some reason or other, Mr. Smith is not a *persona grata* at Whitehall. The persistent manner in which he stuck to the original Canal Boats Bill until he got it passed in the teeth of the Minister nominally in charge of it has not yet been forgotten; and Mr. Smith has never been able to fall in with the official habit of letting things slide indefinitely. He has now to be content with seeing another reap the fruits of his missionary labours in the cause of the canal boatman. It is poor satisfaction to him, no doubt, that Parliament and the press should with one voice have united in bearing their testimony to the value of his work, and in giving him credit in initiating the legislative campaign, which has now culminated in the passing of the Act of this year. Yet, as the rewards of reformers go, this is a great deal; and Mr. Smith may be well assured of general sympathy with him in his present disappointment. The fortunate individual upon whom, in default of Mr. Broadhurst, the President of the Local Government Board has conferred the appointment, which was rightly Mr. Smith's due, has hitherto been unknown to fame. But as manager of Mr. Corbett's extensive salt works at Droitwich—a trade which is still largely dependent upon water-carriage—he must have had abundant opportunities of becoming acquainted with the habits and wants of canal boatmen, and so far there is a certain justification for his appointment. Let us hope that he will make canal boat inspection and regulation a reality instead of a farce.

EUTHANASIA.

ALL humane persons must from time to time be grieved at the amount of suffering daily inflicted on dumb animals at slaughter-houses. Many of us endeavour to repress emotions of this kind by persuading ourselves that such suffering is necessary. The recent experiments of Dr. Richardson, however, go far to prove that there is no reason why animals should not be put to death without the infliction of any pain whatever. It may be remembered that Dr. Richardson first thought his object might be attained by means of the electric shock, but after some trial it was considered that the requisite apparatus could not be brought into general use with safety. He accordingly experimented with

nitrous oxide, carbonic oxide, chloroform, methylene, carbonic acid, bisulphide of carbon, coal gas combined with chloroform—all placed the subjects in the state of insensibility. Perhaps the most satisfactory agent was a mixture of carbonic oxide and chloroform in a chamber charged with this was introduced to dogs, and all in a short time passed from death in a profound sleep without evincing consciousness. Dr. Richardson also administered the same narcotic to sheep, making them unconscious, so that they could be killed without pain; the carcasses bleeding as freely under ordinary conditions, and the meat being un-

UNCERTIFIED DEATHS.

MR. W. C. CLARKSON, the health officer at Bridge, condemns in very severe terms the four deaths should have been registered in the district last year from causes 'uncertain' or 'unknown.' He thinks that it is a disgrace that such things should exist, and doubts the advisability of leaving the matter to the discretion of a coroner. The antipathy to holding *post mortem* examinations in a measure accounts for it, but Mr. Clarkson confesses his inability to comprehend the reasons on which inquests are held. Thus, in a case where a person was found dead in a barn, with a bullet in his head, it was decided that an inquest was superfluous, while in the case of a man who was run over by a cart, in the face of bystanders, injuries from the effects of which he died, and no doubt as to the cause of death, it was necessary to have an inquest. Whether it lies with the coroner or elsewhere Mr. Clarkson hesitates to say, but he very properly adds that any event the system is in obvious need of reform.

THE REGULATION OF MIDWIVES.

THE inquest held recently by Mr. Braxton Croydon into the circumstances attending the death of an infant, aged three days, once more drew attention to the danger of allowing ignorant and inexperienced women to practise as midwives. In the instance a poor person had engaged a woman to attend her in her confinement, and, owing to the unskilful treatment of the midwife, the child literally allowed to bleed to death. In the evidence Dr. P. W. Perkins stated that when he was called in the child was in a state of exhaustion and that the cause of death was exhaustion complicated by hæmorrhage. All the organs were healthy, but for the want of skill displayed by the midwife there was no reason why the child should have lived. Addressing the jury, the coroner said that it was important that cases of this kind should be brought before the public, and that unskilled midwives not only very frequently sacrificed the life of an infant, but also that of the mother, and in the present circumstances they would do well to consider whether the midwife had not made herself amenable to criminal law. The coroner, however, took a lenient view of the case, and returned a verdict of 'Accidental death,' adding that the effect that poor people should not employ uncertified midwives, but should apply to the proper authorities, who will tell them whom to employ, is to be hoped that some attempt will be made during the next session of Parliament to do

passing of a Bill making the examination of all women acting as midwives compulsory, and imposing a severe penalty on any person practising midwifery without having been first certified as competent.

INSANITARY WIGAN.

THE unusual prevalence of scarlatina at Wigan, and its association with overcrowding and neglect of sanitary precautions, has of late been brought into prominence by the local press; and the result of an inquiry recently held into the surroundings of a woman who suddenly died from heart disease will not tend to allay public apprehension. It was shown that for some weeks the deceased, her husband, and five children, had occupied a single room, or rather a cellar; and it was in this place that Dr. L. G. Coombs, who was called in, had to conduct a *post mortem* examination. At that time decomposition had set in, and the stench was sickening. Notwithstanding this hundreds of persons were allowed to view the body, which remained exposed on the bed in the room where the husband and five children had to sleep and take their meals during the whole of Saturday night, Sunday, and Monday morning. Decomposition increased rapidly each hour, and when the jury went to view the body on Monday afternoon the stench was intolerable, the remains not having been confined or in any way disinfected. The jury were unanimous in their condemnation of the neglect of all sanitary precautions, and made a presentment to that effect which the coroner promised should be sent to the proper quarter. The deplorable conditions here brought to light, together with the prevalence of infectious disease, the absence of adequate hospital accommodation, and the existence of grave sanitary defects, clearly show that the Town Council of Wigan have quite failed to appreciate the importance of their functions.

THE LANDING OF INFECTED RAGS.

THE Local Board of Goole have been much exercised to know how to deal satisfactorily with cargoes of rags imported from certain parts of France alleged to be free from cholera, and have appealed to the Local Government Board for their assistance. The Central Board have now replied that it is for the sanitary authority to decide whether the evidence submitted to them in any particular case is such as to satisfy them that the rags proposed to be landed in their district have not come either directly or indirectly from any place where cholera has occurred during the present year, and that they are unable to say what evidence of this kind should or should not be accepted. They remind the Goole authority that their order of August 8 prohibits the landing of all rags from France, unless it can be certified that they have not come from an infected district; and if this order is contravened, it is for them to take proceedings under the Public Health Act. Some of the members of the Goole authority think that an unfair responsibility has been thrown upon them by the Local Government Board, but it is obviously impossible for the officials at Whitehall to decide whether this or that cargo should or should not be landed. Special precautions are now being taken to prevent the landing of rags until it has been shown that they have arrived from non-infected places.

FACTORY LEGISLATION IN AUSTRIA.

A RECENTLY published Blue-book contains an important despatch from Sir A. Paget respecting the regulation of labour in the mines and manufactories of Austria. In May last a number of measures affecting the miners were adopted, the principal points of which are as follows: the actual day's work not to exceed ten hours; children under fourteen years of age not to be employed; children over fourteen and women, only by day. Sunday is to be observed as a complete day of rest. The law regulating the position of workmen in manufactories has also passed its first reading in the Chamber of Deputies, and its more important stipulations refer in the same manner to the hours of labour to be observed. The working day is not to exceed eleven hours; children under fourteen years of age are not to be employed in any regular work; and from the ages of fourteen to sixteen they are only to be employed on such light work as would have no prejudicial effect on their health. Neither women nor children are to be allowed to work at night. Sunday is also to be observed as a complete day of repose, and on Saints' days the workmen are to be allowed sufficient time to attend Divine Service. It is further stipulated that persons under eighteen years employed in the manufactories are to be allowed the requisite time for visiting the evening schools.

'INGENIOUS MALPRACTICES.'

THE sanitary and insanitary houses at the International Health Exhibition were built none too soon. Even if the fairness be questioned of making the one house glorious with dadoes, parquet flooring, and the electric light, at an expense which to the unhappy occupant of the normal suburban house would be simply prohibitive, there can be no sort of doubt as to the value of the exhibits from the point of view of a 'frightful example.' A correspondent of this journal drew attention last June (see p. 613) to the extraordinary ignorance and carelessness displayed by workmen when engaged on sanitary works. And that this is not an isolated experience, or one obtaining in the metropolis only, let the following examples, culled at random from the reports of health officers all over the country, testify. Instances of the kind are, indeed, continually being brought to light by health officers, who have much reason to complain of the deplorable manner in which the sanitary arrangements of dwellings are carried out by builders. Dr. Tripe, in a recent report on Hackney, states that when searching for the cause of periodical outbreaks of illness amongst the occupants of the first-back room of a house, he found that the hopper-head of a stack-pipe was within three inches of the window-sill, and the stack-pipe was connected with the shoulder of the soil-pipe from a water-closet, so that when the window was open the stack-pipe ventilated into the bedroom. At another house, where offensive smells occurred and illness of a low type prevailed, it was found that the bath, washhand basin, and sink-wastes were connected directly with the house-drains, and the hopper-head of a rain-water pipe communicating with the drains was within one foot of a bedroom window. At Barnsley, the wife of a tradesman living over a shop in one of the best streets of the town fell ill with erysipelas, and before she was quite well her husband began with a form of pneumonia suggestive of blood-poisoning, to which

were shortly added erysipelas and inflammation of the joints of a character respecting which there could be no mistake. At first the existence of any possible sanitary defect was denied, but on closer investigation it was found that not only were there two sinks on different floors of the house practically communicating directly with the sewer, and so ventilating the sewer into the house, but also that, by an ingeniously unsanitary arrangement, an old sink under the counter of the shop had been made to catch and detain the outflow from the sink on the first floor, and, in fact, to serve as a sort of cesspool in the house. Speaking of the way in which the old drains of Great Yarmouth have been laid, Mr. Batley, the health officer, in a recent report observes that all sorts of sizes and constructions were sometimes found in the course of one continuous drain. It was no uncommon thing to find a drain falling the wrong way; but in this fault the old ones were not peculiar. Something very like the billowy surface of the sea had been imparted to the levels of many of the drains in the town, but with the unfortunate mistake that the fall of the drain was at the top of the wave. In an old drain on the South Quay the contents had to mount up fifteen inches before they could flow out. In a house served by this drain, some deaths from diphtheria occurred a few years ago. Sanitation may not, indeed, have been understood at the time these drains were laid, but Mr. Batley points out that many drains of recent date are quite as faulty as the old ones, which is the more reprehensible inasmuch as sanitary considerations have been ruthlessly ignored, and the most culpable scamping practised. There are, he adds, modern drain-pipes ending in the sand, house-drains not long enough to reach the sewer, and ventilators only such in external appearance. Dr. Simpson, commenting on the sanitary circumstances of Aberdeen, strongly protests against the slovenly manner in which drainage pipes are laid down and jointed. Scamped work is the order of the day. Scamped work in other trades causing the death of those who depend on the work being thoroughly good and safe, brings the culpable person into considerable trouble; not so with bad drainage, though many lives are lost. This total disregard of all care by workmen is an evil of much magnitude, and it behoves every sanitary official to be on the alert to guard against the perversely unsanitary devices of the local builder. In some districts no drains are permitted to be covered in until they have been thoroughly examined by the surveyor, whilst in others the adoption and rigorous carrying out of building by-laws have led to improvement in the sanitary arrangements of dwelling-houses.

THE SANITARY ASPECT OF DYNAMITE.

MUCH has been heard of the destructive powers of dynamite, which, however, we learn from a remarkably interesting article in the *Cornhill Magazine* for September, are of a more limited nature than is generally supposed. It is, therefore, satisfactory to learn from the same source that it has a wide and useful sanitary effect. In the days of gunpowder blasting in mines, and the old ventilation, we are told, there was an excessive mortality among miners, due to a disease of the lungs known as miner's decline. It was not the ordinary tubercular consumption, but a form developed in many other callings among workers in dusty places, and variously

known as grinder's rot in Sheffield, stonemason's decline, rag-picker's disease, and wool-sorter's asthma. (A considerable amount of information in respect to these diseases will be found in Dr. J. S. Bristowe's lecture on 'Industrial Diseases,' read at the International Health Exhibition, and published in the WEEKLY EXHIBITION RECORD for July 5.) The writer of the article in question points out that since the introduction of dynamite and the common use of the nitro-glycerine compounds, there has been a marked improvement in the miners' health; for though the nitrous fumes of burnt dynamite are dangerous, with dynamite properly exploded nothing of the kind is experienced. Incidentally, an account is given of the Baker Petroleum Works, belonging to Ludwig and Robert Nobel, brothers of Alfred Nobel, the discoverer of dynamite, which seems to show that the value of petroleum for skin disease was known some centuries back, for a quotation is given from the travels of Marco Polo, in which he says, 'The oil is not good with food (certainly not!), but it is good to burn, and is also used to anoint camels that have the mange.'

EXCESSIVE DEATH-RATE FROM DIARRHŒA IN BIRMINGHAM.

SOME little consternation has been occasioned in Birmingham by the increase of the death-rate for the latter part of August to 32.9 per thousand, with a zymotic rate of 14.3. For the corresponding period last year the death-rate was a fraction over 21 per thousand. Inquiry into the cause of this startling increase over the mortality of a month previous, when it stood at about 20 per thousand, showed that of the total number of deaths (266) occurring in that borough during the week ending Aug. 23, 100 were attributable to diarrhœa. Ninety of these were children under five years of age, 60 being under one year; there was one death at the age of thirty-three, six at ages between forty and sixty, and three at sixty and upwards. Nor was the return for the ensuing week, ending Aug. 30, any more satisfactory, the death-rate being 32.2 and the zymotic rate 13.5, with ninety-four deaths from diarrhœa, of which seventy were children under twelve months old. This state of things was considered to need some inquiry, with a view to ascertaining to what the excessive deaths from diarrhœa could be attributed. The alarm occasioned only a few days previously by the reported case of Asiatic cholera which, though it has proved to be but a case of virulent diarrhœa, caused a profound sensation in the district at the time, furnished an additional reason for such action being taken by the sanitary authorities as might be required. Simultaneously with this abnormal death-rate was raised an outcry against the water supplied from the Corporation waterworks. There seems to be no room for doubt that for some days the water was of a greenish slimy character, full of green vegetation which, when subjected to critical examination, proved to be a low form of vegetable life. Analysis showed that, while chlorine and free ammonia were small in quantity, albuminoid ammonia (derived from nitrogenous organic matter) was present in an unusually large quantity, indicating vegetable contamination, and calculated to produce diarrhœa. While the albuminoid ammonia present in the water supplied by the Manchester Corporation, was 0.0078 grains per

f Edinburgh, 0'0049; and of Glasgow, Birmingham it was 0'0164. The Birmingham supply is drawn from two sources, one river supplies, and the other from wells the red sandstone at Aston, Oscott, Perry, and Selly Oak. It appears the green vegetable its origin to the supply from the latter wells. This water is stored in reservoirs in very hot weather, such, for instance, as been experiencing, when the temperature the water rises above 70 degrees, of bright green star-like particles rise from the bottom almost through the whole of the water, and form what look like moss. The only way to effectually this is said to be by covering in the which would cost something like 30,000l.; could, no doubt, be done towards the 'vegetation' getting into the pipes the taps by occasionally flushing the during the height of disturbance this is pressed upon the authorities. But the Dr. Hill, the borough analyst, shows the quality of the Corporation water to be and continually improving, and since the hot weather disappeared there has been of the complaint. With regard to the death-rate from diarrhoea, the authorities uses down in great measure to the eating of or tainted food, and to chills after exertion.

been ascertained that the man George (said to have been from cholera) died in the return for the week ending 1st, had for a number of days before his death partaking freely of some tainted ham, and suffered from premonitory symptoms and they been attended to—would in all have saved his life. One result of the has at all events been to cause increased to be exercised by the sanitary authorities of the town, and the highest Birmingham has had for a very long therefore not be without some advantage to the community at large. It may be mentioned that singular that in the mortality return corresponding month of 1883, twenty-two from diarrhoea included one which was re- 'cholera.'

KAN FEVER AT BIRKENHEAD.

Birkenhead, on September 3, the deputy town clerk issued an order to destroy two carcasses which had been seized at the Foreign Animals Wharf. It was stated that on Sunday (Aug. 31) the steamer arrived in the Mersey from Boston with which she landed at Birkenhead. On inspection it was found that two of the beasts were suffering from typhoid fever, and they were accordingly seized under the provisions of the Public Health Act. The carcasses had been originally made on Sept. 1, but were condemned at the owners' request, in order to prevent them from bringing scientific evidence in proof that the meat was not unwholesome or unfit for food. The witnesses in support of the application were Mr. Vacher, medical officer of health, Mr. P. C. veterinary inspector, Dr. Braidwood, veterinary surgeon, medical officer of health for the Local Board, Mr. Dobie, Mr. Storer, and Mr. Gregory, veterinary surgeons, and Mr. Gregory,

nuisance inspector, who seized the meat. It was contended that an examination of the viscera showed that both the animals were the subjects of Texan fever. The spleens were engorged, and weighed three times the normal weight; the livers were much enlarged and softened, the kidneys were also enlarged and congested, and a quantity of serum effused around them; there were blood extravasations on the surface of the heart and into the mucous lining of the rectum, and (most characteristic of all) there were many irregularly-shaped erosions in the fourth stomachs, the floor of the erosions being black from the necrosis of the mucous coat. The carcasses did not show any special indications of disease. They were bile-stained, as was always the case in Texan fever; but bile-staining might arise from many causes, and did not necessarily render the meat unwholesome. Mr. Vacher, in cross-examination, stated that he had seen many cases of this disease since the first case which arrived in Birkenhead in August 1880. He had uniformly condemned such meat. No less than five carcasses infected thus with Texan fever, belonging to the present defendants, were seized about a month ago, and no objection was made to their being destroyed. Mr. Vacher admitted that, if thoroughly cooked, it was quite possible that such meat might be eaten with impunity. If, however, the meat were underdone, its ingestion would not be without risk, especially if the eater chanced to have a small wound in the mouth.

The witnesses for the defendant were Mr. Marsh, surgeon, member of the Liverpool Town Council, who stated that he examined both carcasses and found no signs of disease, and Dr. Imlach, who stated that he saw no indication of disease; there were no abscesses in the livers, nor any indication of lung disease. Neither of these witnesses had ever seen a case of Texan fever, and the viscera had only been examined by them on the 2nd (about fifty-four hours after the slaughter of the animals).

The stipendiary magistrate, after hearing this conflicting evidence, decided to go to the slaughterhouse and himself inspect the carcasses; and, finding the meat seemed firm to the touch and had no offensive smell, suggested that the Corporation should withdraw their application, and ultimately this was agreed to. The magistrate thought that as both sides were anxious to have a test case it would be better to wait till another seizure was made, when arrangements might be made for the scientific witnesses all seeing the viscera in a fresh state. In the present instance the medical men called for the defendants did not appear to have made their examination till the morbid appearances relied on were effaced, or partly so, by decomposition.

SANITATION AT THE HOUSES OF PARLIAMENT.

DISAGREEABLE smells having been noticed to pervade the 'House,' a select committee, consisting of Mr. W. H. Smith, Sir Lyon Playfair, Sir Joseph Pease, Mr. Giles, and Dr. Farquharson, has been appointed to inquire into the cause, and in the report it is stated that the smells complained of do not arise from any deficiency in the sanitary arrangements, and that the condition of the sewers and drains is entirely satisfactory, and reflects great credit upon the officers who are in charge of the building in their several departments. No complaints have been made as to the operation of the

system of ventilation, which appears to be entirely satisfactory; but it is clearly impossible for any method of ventilation to prevent the entrance of offensive smells which pervade the atmosphere outside the House; and from the evidence which has been brought before the committee it is clear that the smells proceed from sewer gas in the vicinity, and from some other cause, more remote, which they have not had time or opportunity fully to trace, although it is shown that these noxious objections are believed to proceed from dust heaps, the burning of refuse, and from gases emitted in the course of manufacture by factories within a distance of a few miles from the neighbourhood, and that great complaints have also been made from other parts of the west of London. It has not, however, been yet specially suggested that the condition of the Thames may have added to the prevailing nuisance, and it is quite probable that this cause may be included. Evidence has also been given that the local sewer under the control of the Westminster District Board of Works emits most offensive smells from time to time, and the committee are of opinion that steps should be taken by the local authority to put an end to a nuisance of a very serious character. It is also recommended that an officer of the Local Government Board should be directed during the recess to observe the emission of the noxious smells in the district referred to, and to take steps to trace them to their source, and the report concludes with a recommendation that the committee should be re-appointed during the next Parliamentary session to consider such further evidence as may be obtained. The present minutes of evidence so far have not been published, but we believe it is the intention so to do, and as they are likely to throw considerable light upon the subject we shall refer to it again. It may be mentioned that amongst those examined were Dr. Percy, Mr. Henry Doulton, and Sir Joseph Bazalgette, the engineer to the Metropolitan Board of Works, and we may therefore be assured that the question has been well discussed from all points of view.

THE UTILISATION OF REFUSE.

THE question of the disposal of house and street refuse is of ever-growing importance, as the more that waste land becomes restricted the nearer to our habitations are the heaps of refuse deposited, and the mischief caused by building houses on sites formerly used for this purpose is too well known to doubt. Any steps in the direction of satisfactorily disposing of or converting such poisonous material as this soon becomes, into a harmless substance is greatly to be welcomed. It has been suggested to transport such refuse to different parts of the low-lying east coast, and to saturate it with sewage, with an overflow to the sea for the more fluid portion thus created. This might be a nucleus for a large extent of grass land, but it is a question whether this process would not be a nuisance in itself, in addition to which there are no facilities existing to carry out such a scheme, and the consequent expense would be enormous. Experiments are now being made in the provinces and also near London to burn and carbonise such material as would be difficult otherwise to get rid of in an unobjectionable form. (See p. 119.) Vegetable matter is, of course, by these means easily reduced to charcoal, but road sweepings in London in wet weather contain 43 per cent.

of abraded stone and iron, and these, with other mineral substances which would be included in the general dust-heap, can be burned and ground to form a good building mortar, and from recent experiments it has in some cases been found to pay for the cost of so doing, although as a general rule it cannot be said to be a remunerative undertaking to dispose of town refuse of this description. This difficulty probably arises from the small way in which such experiments have been carried out, and it seems probable that, if conducted on a larger scale in the principal towns, a good commercial result might be obtained, more particularly if the sanitary value is taken into account as a valuable asset on the credit side.

THE ENGINEERING STAFF AT THE LOCAL GOVERNMENT BOARD.

A CAPTIOUS but well-informed correspondent sends us the following as to the composition of the Engineering Department of the Local Government Board. His remarks are too personal to be altogether fitted for our columns, but as there appears to be some truth in what he says, we print his criticisms for what they may be worth:—

I wonder if any of your readers besides myself have noticed the extraordinary frequency with which the name of Mr. John Thornhill Harrison has of late appeared in the newspapers as the inspector appointed by the Local Government Board to solve this and that other engineering problem. Apparently when the board finds itself in any specially awkward predicament in which sewage and sewage disposal are concerned, they have to fly to Mr. Harrison for advice. Certainly they could not do better; but when we learn that Mr. Harrison is to inquire into the sewerage of the Lower Thames Valley, that Mr. Harrison is to investigate the state of the Thames at the sewage outfalls, that to Mr. Harrison has been assigned the high and noble duty of tracking to their lair the effluvia that have ventured into proximity with our legislators' nostrils, one is apt to ask whether, much as we have only one general in the army, we have only one sanitary engineer in the service of the State. Probably the very moderate salary which falls to the lot of the engineering inspectors who scour the country in giving sanctions to loans, accounts for the mediocrity of the department as a whole. Honourable mention must indeed be made of the past services of its chief in the days when sanitary reform was something of a byword; but when a gentleman arrives at the age of seventy-four one begins to look upon him as past work—at any rate, such work as the occupant of this particular office is called upon to do. The other members of the staff are the brother of a well-known novelist and whilom secretary of the department, who is better known for his conversational powers than for his erudition as an engineer; an ex-secretary of a Royal Commission, remarkable chiefly for his frequent appearances in local newspapers (to-day at Exeter, to-morrow at Newcastle) in the character of an official punster; a former inspector of turnpikes in South Wales; and a couple of 'heavies'—a major and a captain—from the Royal Engineers. With colleagues such as these, Mr. Harrison's selection for the difficult and responsible duty of advising on the measures to be adopted for the purification of the river is hardly to be wondered at. If I were Mr. Harrison, which providentially I am not, I should turn faint at the bare mention of the Thames. Last year he had to conduct an inquiry into a request for a Provisional Order by the Lower Thames Valley Sewerage Board, which lasted an enormous length of time, produced 'evidence' which ran the Tichborne trial dangerously close for size and complexity, and finally ended in nothing. He has now to go over the whole of

this ground again, and to devise a scheme for the purification, not only of the upper reaches, but also for the more effectual disposal of the millions of gallons of sewage that are now daily discharged into the river at Barking and Crossness. Who will not pity him in this thirteenth hour of Hercules? The cleansing of the Aegæan stable was absolutely elementary in comparison.

INFANTILE MORTALITY.

At the last monthly meeting of the Gateshead Corporation the death-rate of the borough for the previous month showed an average of 30 in the 1,000 per annum, 67 out of the 169 deaths that occurred being those of children under one year old. An animated discussion took place as to the cause of this excessive infantile mortality, which was ascribed to autumnal diarrhoea to some extent. Mr. John Lucas said that it was a lamentable fact that the primary reason was that the great bulk of the people were entirely ignorant of how to rear an infant. He said they might spend some part of their time profitably in teaching the people how to bring up their children. Alderman Charlton said if they could keep women more within their own doors, and prevent them gadding about and drinking with their neighbours, he had no doubt but that it would tend to diminish this frightful infantile mortality. Mr. Councilor Parkin attributed the excessive death-rate to the common practice of feeding children with read 'boiley.' Alderman Affleck gave his opinion that the present system of ashpits was the cause of the high death-rate, and it was ultimately resolved that the Town Improvement Committee make an inquiry as to the advisability of adopting a new plan for the removal of the ashpit refuse.

THE Yeovil Town Council and Urban Sanitary Authority have determined to establish public baths, at an estimated cost of between £200 and £300.

If any one desires to vex his soul by ascertaining the exact language of the Acts of Parliament under which taxing powers are claimed by the several Metropolitan Water Companies, he may be recommended the perusal of Parliamentary return (No. 108) recently issued on the motion of Lord St. Leonards. The various Parliamentary enactments are given without the smallest attempt at classification or explanation, and we fear that the return will puzzle rather than assist the untutored ratepayer. Attached to the return is a sprawling and awkward, but otherwise useful, map, showing the districts supplied by each company and its Parliamentary limits.

A CONTRIBUTION to the *Glasgow Herald* attributes the success of over-pressure in Scotch schools—although the standard of education is high—to the superior physique of Scotch children, through their being so largely fed on oatmeal. The writer thinks it beyond dispute that no other food for children equals oatmeal. It makes bone and it takes brain, and it may, he believes it probable, give the sustaining power that enables the Scotch child to stand the work that, under different diet, would result in strain.

THE United Operative Plumbers' Association of England and Ireland now numbers 2,349 members, being an increase of 229 on the year, and has 81 lodges in 80 shire towns, including 9 in Scotland. The society comprises the features of a trade union with those of a sick benefit and accident society, in which members' wives participate. The funds of the society now amount to 1,928*l.* or 6½*d.*, of which 1,646*l.* 5*s.* 11*d.* forms a permanent reserve fund. Liverpool contains the largest number of members, namely 141; while London, including Lewisham, figures for July 14.

THE PUBLIC HEALTH

DURING AUGUST 1884.

THE mean temperature during the month of August at the Royal Observatory, Greenwich, was 65°·3; it was 4°·5 above the average August temperature in one hundred years, and exceeded that recorded in the corresponding month of any year since 1857. An excess of temperature prevailed on twenty-three days of the month, while on the other eight days it was below the average. The warmest day of the month was the 11th, when the mean was 77°·2, and showed an excess of 14°·5; the coolest day was the 26th, when the mean was only 53°·8, and 7°·1 below the average. Rain was measured at Greenwich on eight days during the month, to the aggregate amount of only 0·7 of an inch, which was less than a third of the average August rainfall in sixty-one years. During the first eight months of this year the rainfall amounted to 11·4 inches, which was as much as 4°·4 below the average rainfall in the same period of sixty-one years. The sun was above the horizon during 449·1 hours in August, and 203·4 hours of bright sunshine were recorded at Greenwich; this amount considerably exceeded that registered in the corresponding period of any year on record. The wind was very variable throughout the month.

In the twenty-eight large English towns dealt with by the Registrar-General in his Weekly Returns, which have an estimated population of nearly eight millions and three-quarters, 22,395 births and 16,260 deaths were registered during the four weeks ending the 30th ult. The annual birth-rate, which in the three preceding months had been 35·5, 34·6, and 34·0, further declined to 33·3 during August, and was slightly below the rates recorded in the corresponding month of the two preceding years, 1882 and 1883. In these twenty-eight towns the lowest birth-rates last month were 29·1 in Huddersfield, 30·2 in Bradford, and 30·7 in Bristol; the rates ranged upwards in the other towns to 39·1 in Newcastle-upon-Tyne, 40·4 in Hull, and 44·0 in Cardiff. In London the birth-rate last month was 32·2 per 1,000, while it averaged 34·3 in the twenty-seven provincial towns.

The annual death-rate in the twenty-eight towns, which had been 19·3 and 22·8 in the two preceding months, further rose, owing principally to the increased fatality of diarrhoeal diseases, to 24·2. This rate considerably exceeded those recorded in the corresponding months of 1882 and 1883, which were 22·0 and 19·5 per 1,000 respectively. The lowest rate of mortality last month in these towns was 17·4 in Bristol. The rates in the other towns, ranged in order from the lowest, were as follow:—Derby, 19·2; Huddersfield, 19·7; London, 20·7; Brighton, 21·7; Bradford, 22·7; Birkenhead, 23·1; Plymouth, 23·7; Sunderland, 24·5; Newcastle-upon-Tyne, 25·8; Portsmouth, 26·4; Sheffield, 27·8; Hull, 27·9; Salford, 28·0; Manchester, 28·3; Oldham, 28·4; Birmingham, 28·7; Leeds, 28·7; Nottingham, 28·7; Liverpool, 28·9; Norwich, 28·9; Blackburn, 29·2; Halifax, 29·3; Cardiff, 29·5; Leicester, 30·6; Wolverhampton, 31·5; Bolton, 32·2; and the highest rate during the month, 34·3 in Preston. While the death-rate in London during August, as above stated, did not exceed 20·7 per 1,000, it averaged as much as 27·2 in the twenty-seven provincial towns. The 16,260 deaths from all causes in the twenty-eight towns during the four weeks of August included 4,593 which were referred to the principal zymotic diseases, of which 3,336 resulted from diarrhoeal diseases, 320 from measles, 289 from whooping-cough, 256 from scarlet fever, 218 from 'fever' (principally enteric), 90 from diphtheria, and 74 from small-pox. These 4,593 deaths were equal to an annual rate of 6·84 per 1,000. This zymotic rate showed a further considerable increase upon those recorded in recent months, owing to the fatal prevalence of summer diarrhoea in most of the towns; it was also much above the rate from the same diseases in the corresponding period of either of the two preceding

years. The zymotic death-rate in London during August was 4.76 per 1,000 (of which 2.85 was due to diarrhoea), while in the provincial towns it averaged as much as 8.59, of which 6.76 was due to diarrhoea. The zymotic rates in the provincial towns ranged from 3.0 in Huddersfield, 3.3 in Bristol, and 3.8 in Plymouth, to 12.2 in Leicester, 12.5 in Preston, and 12.8 in Wolverhampton.

Diarrhoea was the most fatal zymotic disease in the twenty-eight towns throughout the month of August. The rate of mortality from this disease in these towns, which had been 3.67 in July, rose to 4.97 during August, and considerably exceeded that recorded in the corresponding month of 1883, when it was only 1.90 per 1,000. The diarrhoea death-rate last month did not exceed 2.12 in Bristol, 2.27 in Huddersfield, and 2.94 in Plymouth; while it ranged upwards in the other towns to 9.35 in Birmingham, 10.62 in Preston, 11.11 in Norwich, and 11.30 in Leicester. While the rate of mortality from diarrhoea did not exceed 2.85 per 1,000 in London, it averaged as much as 6.76 in the twenty-seven provincial towns. The death-rate from measles, which had declined in the three previous months from 0.94 to 0.64 per 1,000, further fell to 0.49 during August. The rate of mortality in London from this disease was 0.43 per 1,000, and among the provincial towns the highest rates were 2.60 in Blackburn and 2.73 in Halifax. The rate of mortality from whooping-cough was equal to 0.43 per 1,000; it showed a marked further decline from the rates in recent months, and was 0.12 above the rate recorded in the corresponding period of last year. In London the death-rate from this disease was slightly below the average of the provincial towns, among which the highest rates were 0.98 in Liverpool, 1.19 in Halifax, and 1.27 in Sunderland. The rate of mortality from scarlet fever, which had been 0.35 and 0.44 per 1,000 in the two previous months, declined again during August to 0.38. The death-rate from this disease in London was 0.34 per 1,000; in the provincial towns it averaged 0.42, and showed the largest proportional fatality in Wolverhampton, Sheffield, and Cardiff. The death-rate from 'fever' (principally enteric or typhoid) showed a further increase upon that recorded in recent months, and was slightly higher in London than in the aggregate of the provincial towns. The rate of mortality from diphtheria showed a decline from the rates in recent months; the fatality of this disease was principally confined to London, where 70 of the 90 deaths in the twenty-eight towns were registered. During the four weeks of August 74 fatal cases of small-pox were registered in the twenty-eight towns, showing a further considerable decline from those returned in recent months; of these, 58 occurred in London, 6 in Sunderland, 4 in Liverpool, 3 in Sheffield, 1 in Birkenhead, 1 in Hull, and 1 in Cardiff. Judged by the returns of the Metropolitan Asylum Hospitals, the prevalence of small-pox in London showed a further considerable decline during August. The number of small-pox patients under treatment at these hospitals, which had been 1,290 and 892 at the end of the two preceding months, further fell to 539 at the end of August. The average weekly number of new patients admitted to these hospitals, which had been 275 and 151 in the two previous months, further declined to 73 during August.

The rate of infant mortality in the twenty-eight towns, measured by the proportion of deaths under one year of age to births registered, was equal to 280 per 1,000 during August, against 226 and 177 in the corresponding periods of the two preceding years, 1882 and 1883. The excessive fatality of summer diarrhoea in many of the towns caused this unusually high rate of infant mortality. While the rate did not exceed 187 and 208 in Bristol and Huddersfield, where the lowest death-rates from diarrhoea were recorded, it ranged upwards in the other towns to 416 in Preston, 421 in Brighton, and 452 in Norwich, in each of which towns diarrhoea was fatally prevalent.

The death-rate from diseases of the respiratory organs, judged by the metropolitan returns, was slightly above the

average during August. The number of deaths referred to these diseases in London averaged 172 weekly, and the annual death-rate was equal to 2.2 per 1,000. The annual rate of mortality in Liverpool from these diseases was last month equal to 2.3 per 1,000.

The causes of 386 of the 16,260 deaths registered in the twenty-eight towns during the four weeks of August were not certified, either by medical practitioners or by coroners. These uncertified deaths were equal to 2.37 per cent. of the total deaths, which exceeded the proportion in recent months. In London the percentage of uncertified deaths did not exceed 1.14, while it averaged 3.17 in the twenty-seven provincial towns; all the causes of deaths were duly certified in Norwich and in Derby throughout the month, while the largest proportions of uncertified deaths were returned in Liverpool, Oldham, and Halifax.

Among the population living in the outer ring of suburban districts around London, estimated at rather more than a million persons, the annual rate of mortality during August was equal to 20.5 per 1,000, against 17.2 and 15.4 in the corresponding periods of 1882 and 1883. During the four weeks ending the 30th inst., 346 deaths from diarrhoeal diseases, 45 from whooping-cough, 26 from small-pox, 18 from diphtheria, 15 from measles, 15 from 'fever,' and 8 from scarlet fever were recorded in the outer ring. These 473 deaths were equal to an annual rate of 5.7 per 1,000, which considerably exceeded the rate recorded in the same period of any recent year. The fatality of small-pox and diarrhoeal diseases showed a further increase, while that of measles and whooping-cough showed a decline. Of the 26 deaths from small-pox, 20 were recorded in West Ham and 6 in Edmonton.

NOTIFICATION OF INFECTIOUS DISEASE.

IN the following table are published uniform statistics of sickness and mortality in thirty of the thirty-eight urban sanitary districts in England and Scotland wherein the notification of infectious disease is compulsory. The estimated population of the thirty towns in the accompanying table, for which we are enabled to publish complete statistics for the month of August, is about two and a half millions of persons. The annual rate of mortality from all causes, per 1,000 persons estimated to be living in these towns, was equal to 23.41, against 19.53 in the preceding month. This increase in the mortality was mainly due to the greater fatality of diarrhoeal diseases. In the twenty-eight large English towns dealt with by the Registrar-General in his Weekly Returns the mean death-rate during August was equal to 24.21 per 1,000, which exceeded the rate in the towns in the accompanying table. The death-rates were considerably below the average in Aberdeen, Derby, Dundee, Greenock, Macclesfield, and Reading; while they showed a marked excess in Bolton, Jarrow, Leicester, and Preston. The high rates in each of these last-mentioned towns was principally due to the fatal prevalence of summer diarrhoea. The rate of mortality from the eight infectious diseases dealt with in the table averaged 0.54 per 1,000 in the thirty towns which furnished this information, and showed a slight decline from the rate recorded in the preceding month. No death from any of these diseases was recorded during last month in Derby, Leek, Macclesfield, Reading, and Warrington, while they caused the highest death-rates in Heywood, Rotherham, and Salford. With reference to the notified cases of infectious disease, it appears that the average proportion of the population reported to be suffering from one or other of the eight diseases was 4.07 per 1,000, against 3.86 per 1,000 in the preceding month. No case of any of these diseases was notified in Heywood during August, and only 1 in Rotherham; the proportions in the other towns ranged from 0.97 and 1.04 per 1,000 persons living in Stalybridge and Accrington, to 7.56 in Leicester, 7.75 in

Dundee, 7·78 in Salford, and 9·71 in Leek. Scarlet fever showed the greatest proportional prevalence in Jarrow, Leicester, Salford, and Dundee; enteric fever in Edinburgh, Salford, Blackburn, and Greenock; typhus in Aberdeen; and diphtheria in Dundee. Cases of small-pox were notified in Aberdeen, Birkenhead, Bolton, Bradford, Leicester, Nottingham, and Salford. Three cases of puerperal fever, and 2 deaths, were returned in Dundee.

SPECIAL REPORTS.

NEW REFUSE DESPATCH WORKS AT GLASGOW.

THIS is the second enclosure in Glasgow fitted with suitable machinery and appliances for dealing with and despatching daily, as collected, the heterogeneous refuse of the city. The objects which the Cleansing Committee of the Magistrates and Council of Glasgow have had in view in its construction are chiefly:—(1) To have each day's collection of refuse despatched to the country directly as it is brought in by the scavenging carts, and thus do away with the storing depôts in the city, which the authorities and the citizens generally have been so anxious to see abolished; and (2) to have the refuse dealt with and loaded mechanically, so that only the manurial portion, freed of all rubbish, will be sent to the farmers, while of the non-manurial portion, everything which can be sold or utilised with advantage will be turned to the best account, and the remainder reduced to inoffensive clinkers by cremation. The first work of the kind in Glasgow was started three years ago, and is constructed on the same lines, but with improvements which experience has suggested. The principle adopted in the new Refuse Despatch Works is to have refuse of all sorts carted in to the highest point, so that, without the use of elevators, the whole material is mechanically dealt with as it descends—the manurial portion being delivered into the railway waggons, the cinders in front of the boilers, other articles for use or sale—such as old iron, meat tins, old boots, &c.—to places appointed for them respectively, and all other unsaleable rubbish into cremating furnaces. The area of ground occupied (including street) is 5,100 square yards. The machinery house proper is a substantial three-storey building, 117 feet by 91 feet. All the carts on entering the gatehouse pass on to the weigh-bridge, and are weighed by the gateman. Any material—such as stable manure, which requires no manipulation—is carted straight into the middle floor, where closed hatches are provided for simply shooting it into the railway waggons. All the general city refuse, which is composed of—(1) contents of ashpits and bins, (2) excreta, and (3) street sweepings, is taken to the top floor, where special provision is made for each variety. The contents of ashpits and bins—these forming, of course, much the largest quantity—are shot into revolving screens of new design, erected close under the girders. Each screen (making fourteen revolutions per minute) has a double action, and although in one piece is practically a screen within a screen. By the first action upon the inner mesh, sloping from west to east, all the rougher rubbish—which will not pass through a 1½ inch opening—is separated and delivered on to a travelling carrier at the east end of the screen; and by the second action upon the outer mesh, sloping in the opposite direction, the material which has passed through the inner mesh travels back over the ½-inch outer mesh. The material—chiefly cinder—which passes over this ½-inch mesh is delivered at the opposite end of the screen from the rubbish, and is thereafter passed down a shoot to the front of the boilers, where it is used as fuel, and serves to raise steam for the works. The fine ash and small manurial particles fall through both meshes of the screen and thence down a shoot into mixing machines, which stand upon an elevated platform on the floor immediately below. Into these mixers there passes at the same time a mechani-

cally regulated quantity of excreta. The cart in which this material is collected also ascend floor, where the contents are passed through glass closed cast-iron tanks, which rest on the second floor from which, by a simple mechanical arrangement, desired supply is allowed to escape into the mixer with the fine ash, which absorbs and deodorises in order to fix the ammonia and further deodorise pound, provision is made for adding sulphur or other disinfectant or deodorant to the excreta in The other material which is shot into the mixer consolidated detritus from the paved streets &c. In our wet climate this is frequently collected in a very slushy condition and in large quantities sloperry sweepings are also carted to the top floor provision is made for having them shot through openings near the gables into large cast-iron tanks draining tanks are of novel construction and designed for this purpose. They have sloping bottoms provided with apparatus for draining off the water pressed to the surface. When the contents are drained the large doors in the front are gradual means of chain barrels and worm gear, and the material which is pulpy and rich looking, is shot down into the mixers. Thus the various manurial portions of the refuse are passed in regulated quantities into mixing machines, whose revolving blades throw the whole into a deodorised compound, which is then shot into the railway waggons direct, and the fine material supplied with a prepared manure in good condition for spreading on the land. The rough rubbish, as observed, is delivered by the inner screen on to a travelling carrier. This is an endless web of iron plates with chains, which is made to travel 30 feet per minute. Women are stationed in front of it to pick off what can be sold or utilised. One picks off what is manurial, such as dirty straw, pulpy material, table refuse, &c., and this garbage she drops down by her side into the wagon direct, where it is mixed with the compound as it comes from the mixer. Materials picked off for use are old iron, old tins, rags, paper, &c. The remainder is shot down the carrier into a specially constructed cremating furnace, where it is reduced to clinkers, which are, of course, sold, and, like common furnace ashes, go to make up ground. The various articles of salvage available are mostly sold to persons who can make use of them. Old iron goes for precipitating copper; ammunition is extracted from old boots; solder is taken from old tin cans and so on. The scrapings of macadamised roads are not mixed into the prepared manure for sale, but the material is drained separately at the south end of the works and despatched by itself to the reclaimed farm at Moss, for the improvement of which it is used. There are four sets of rails running inside the works with a traverser at the north end for shifting waggons, the one set to the other; and provision is made for all the traversing and haulage by steam-power. The erection of the works special attention has been given to the question of ventilation. A very large fan, driven by a separate 30 horse-power engine, and capable of moving 29,000 cubic feet of air per minute, is made to draw constantly from the soil and mixing chamber, and blow the vitiated air through large pipes leading to the ashpits of the cremating furnaces, thus supplying them with air under a slight pressure. This is a thorough way of dealing with it, and of preventing any nuisance outside the building. For light and ventilation a large opening or well, 31 feet by 31 feet, is left near the centre of the building, immediately above the cremating furnaces. A large bell-mouth, 10 feet in diameter, is hung from the roof over this well, and connected by a 3-foot sheet-iron flue to an annular space in the roof. This draws off the vapours which are the process of cooling the red hot clinkers within the furnaces and boilers, thus keeping the bu-

ar from sweating. The chimney is 250 feet in 20 feet diameter at the base, and 10 feet diameter top. Steam at 60 lbs. pressure is raised by means under fuel in two Lancashire boilers of 50 horse-power. The machinery—all in duplicate—is driven by high-pressure coupled horizontal engine capable of doing 80 horse-power. The cleanliness and comfort of the workpeople of both sides have not been forgotten, suitable lavatories and bathing facilities have been provided for them, and also messrooms for necessary cooking and heating conveniences. There has also been made for the district carting department of the department on the same piece of land by making stabling accommodation for thirty-four and their harness, with the necessary cooking and arrangements. Under the stables, which are raised over-work and approached by an inclined gangway, are large storage-sheds for carts and other vehicles, and in the small open yard in front of these provisions is made for hose-washing the carts as they go in. Over the stables there are commodious straw lofts, and close to the gatehouse there are g-houses for the works manager and the carting men respectively. The works have been planned, and their erection supervised, under the cleansing committee by Mr. Young, inspector of cleansing, and his assistants.

At the luncheon given on the opening of these works, the Provost of Glasgow stated that the cleansing department had 163 miles of streets and roads to cleanse, and 700 tons of all manner of refuse were collected daily. Last year the refuse of the city was sold to customers, scattered over no fewer than sixteen parishes. The Cleansing Committee had made a farm out of it, and it was now paying in crop. They employed between 800 and 900 men, including almost all the tradesmen, and owned 180 horses. Mr. Young and his officials passed upwards of 100,000 lbs. of their hands annually, exclusive of what had been done in the new works.

REVIEWS.

EXHIBITION HANDBOOKS.

Sanitary and Unhealthy Houses in Town and Country. By W. Eassie, C.E., F.L.S., F.G.S., &c. With Appendix by Rogers Field, B.A., M.Inst.C.E. Illustrated. London: Clowes & Sons.

Formerly, aspect and geological conditions of site were supposed to constitute the main essentials for determining whether a house could be rendered healthy or the reverse; so, recently, have these points been almost entirely neglected, and attention has been transferred to the question of 'immediate house-drains,' and therein are supposed to lie the main facts. As usual, the mean between extremes is nearest the truth, and although there are technical works bearing upon the subject, we are enabled to find that aspect, subsoil, distribution of air, and ventilation are not lost sight of in this concise and useful manual. Coming under the heading of a highly practical work, it is unusually free from technical terms, and, though it may be read with advantage by sanitarians, it still is written in such a way as to be fully understood of the people.

The author's freedom from unpractical theory is apparent from the beginning, where it is admitted that fairly good sites can be provided upon any of the geological formations, otherwise it would be a very serious matter for us that have no choice, and this inability to choose, we are in the position of the majority of people. Attention is called to the curious fact that the earliest civilisation on our island chose the outcroppings of only certain geological formations to almost the entire repudiation of the In the eastern part of Northumberland the ancient

villages and hamlets were built only upon certain isolated areas of a certain sandstone. Out of twenty-three villages, thirteen were built upon rock, six upon sand, and only one upon the clay. It has also been pointed out that no less than nineteen of the largest and most important towns in England, from Exeter to Carlisle, are all situated along the line of one geological formation, the new red sandstone. Most people prefer gravel for a subsoil, and rightly so, provided that the gravel is sufficiently extended to allow of natural drainage and percolation, otherwise, if the area of gravel is limited, or not deep enough, its absorbent properties will produce ill effects if an understratum of impermeable clay or rock should form a barrier to drainage, and in preference to this the author recommends building upon a hard clay, making provision against damp and stagnation by means of concrete and draining.

The evil of damp walls arising from the want of a damp course is also adverted to, and the usual plan of putting a 'dry area' between the house wall and the earth is advised; but for the damp course we must take exception to the use of slates bedded in cement, or even the special made tiles; the slates, particularly, are very unsatisfactory for this purpose, they crack at the inevitable settling of a new wall, and thus add to the already too numerous joints. A good layer of asphalt is the best for this purpose, and where this cannot be readily obtained (as is often the case in the country and for small works), the best plan is to use a damp course of sheet lead, which possesses the advantages without the disadvantages of the other methods. The many insanitary points of construction and arrangement well known to professional men are taken in order, and the main portion of the work is devoted to the house-drains and connections. These are treated of very fully and impartially, and lead naturally to the 'Appendix' on *The Water Supply and Disposal of Sewage of Country Houses*, by Mr. Rogers Field. In a comparatively short space the first question is clearly dealt with, the sources of supply, rainfall, springs, and wells are taken *seriatim*, and useful notes and memoranda are given. There is a point mentioned to which attention might more frequently be drawn with advantage, viz., that 'rain water, on account of its softness, frequently has a strong action on lead, and that leaden pipes and cisterns should therefore never be used in connection with it. The best material to use for the pipes is iron, or, in some instances, 'lead-encased block tin pipe,' in which the tin is not a mere coating, but of a sufficient thickness to protect the lead satisfactorily. This latter point is of the utmost importance, as, if the tin were perforated or broken through, the danger of the lead being acted on would be increased in consequence of galvanic action being set up. The expense of this tin-lined pipe is, unfortunately, against its general use; it costs half as much again as the ordinary lead description, and is much more difficult to work.

The sewage distribution is discussed from all sides, and its disposition over the land in small quantities points to a sensible conclusion.

The 'get up' of these Exhibition handbooks is scarcely distinguishable from the catalogues, and, as they are well illustrated, they should become useful references; as such they are entitled to a permanent binding, by means of which they can be preserved, otherwise they are apt to lose the covering title-page, and with it they lose their identity and become lost among pamphlets or even unwittingly are allowed to drift into the waste-paper basket.

Health in the Workshop. By James B. Lakeman, H.M.'s Senior Metropolitan Inspector of Factories, Home Office. London: Clowes & Sons.

If the majority of operatives are unacquainted with the history of factory legislation, it can scarcely be expected that the public should have much knowledge of the subject, and to make us acquainted with the present extensive safeguards of the health and physical protection of the workers, Mr. Lakeman traces the Acts and results from

the time 'when George III. was king' to the year of grace 1883. Starting in 1802 with 'small beginnings and modest phrases with gentle interference,' we find that fresh Acts and amendments were gradually introduced until at last they control or regulate every industry great or small. The first Act related mainly to the wants of apprentices as to clothing, cleanliness, and ventilation; time for work and meals was regulated, and their morals cared for. The principles of religion were duly instilled once a week, and every apprentice was to receive the Sacrament before he attained his eighteenth year. These provisions apparently were not fully carried out, and after a time the increasing number of factories and fresh industries gave rise to further evils, and in 1833 the second Act was passed with wider powers and scope, but morals in this case were not mentioned, as there was so much cruelty and iniquity to be overcome before morality or religion could receive consideration. In another ten years it was necessary to introduce further regulations, and the safety of life and limb from machinery had to be provided for. In 1846 the Print Works Act was passed, as it was shown that children were made to work at the age even of five years, and that too for fourteen hours a day in a temperature sometimes reaching 110° Fahr. In 1848 the working hours were reduced to ten per day, but ten consecutive hours were allowed, commencing at any time, so that night work was not excluded. These rules being evaded, it was enacted that young people and children's time should be limited from six in the morning to six at night, and to two in the afternoon on Saturdays, meal times being also noticed. It will be seen that up to this time, a period of fifty years, the welfare of children and females in textile factories only was considered, but from 1860 to the present time various new Acts, and the repeal of some of the former ones spread the meshes of the inspectors' net in such a way as to reach nearly all for whom legislation in this direction is required. Lace-making having assumed such importance in 1861, a special Act was passed to bring this industry under the then existing Factories Acts. At that time 150,000 persons were engaged in its manufacture, between 8,000 and 10,000 being children and young persons. Youths between sixteen and eighteen years of age were allowed to work between four in the morning and ten at night, but for nine hours only.

This being a strictly practical work, no attempt is made to refer to the history of any industry, but it may be of interest to many of our readers to remind them that this was not the first time that the Government had the question of lace brought before them, but of course from a different standpoint. In the sixteenth century this delicate fabric was made in England and all over the Continent by nuns and members of wealthy families, and in 1662 the English Parliament, alarmed at the sums of money sent out of the country for the purchase of foreign lace, prohibited its importation. The English lace merchants, at a loss how to supply the Brussels lace required at the court of King Charles II., bought up all the choicest lace in Brussels and smuggled it over to England. The contrast is curious, both in legislative and other points of view.

The impartiality of the enactments is shown by the passing of the Exemption Act in 1871, in favour of the Sunday employment for Jews, otherwise they would be limited to four full working days a week.

The condition of many of the metropolitan bakehouses was made known in 1881, and it will be remembered that terrible facts were disclosed; therefore in 1883 an amended Act was passed to bring them under the necessary inspection, with, it is needless to say, good results.

Part II. deals with accidents, their causes, and extent, and very extensive they appear to be, notwithstanding the many precautions taken to avoid them, but it must be said that the carelessness of the operatives renders many of the safeguards useless, and those who are accustomed to deal with large numbers of men are well aware of this fact.

Part III. deals with the sanitation of factories and work-

shops, and the methods used to prevent the ill-carrying on injurious and noxious trades. The are far too numerous to mention, but a short study to the book will show how necessary it is to those who cannot help themselves; it will also be well they are looked after, and how many are set the wheels of the industrial juggernaut. Ventilation is treated in Part IV., and the question of cubic space is told, not yet satisfactorily settled, owing to the involved; but otherwise the temperature and cleanliness of the atmosphere can be fairly maintained, and this point, considering the many evils to be overcome, the subject generally has been well considered. Before us in an interesting way, it would have a great advantage to the general reader to have a few more illustrations to refer to, particularly in section.

A Manual of Ventilation, Warming, and Lighting.
Capt. DOUGLAS GALTON, C.B., F.R.S. Illus-
trated by London: Clowes & Sons.

WITH many people the word 'ventilation' opening the windows and sitting in a draught, and the poorer classes it implies increased cold and discomfort. The object of this manual is to add to the knowledge of how to obtain fresh air and warmth suffering from the many disadvantages usually incurred in so doing. It is hardly to be expected much fresh information can be given upon a subject which has already been well 'ventilated,' and theory and practice are well described, and the improvements to date show that the question has been consistently elaborated. The majority of works on the subject insist that the public *shall* carry out the and it is assumed that the public possess the means to do so, but in the example before us we are told what *can* and *may* be done. Again, the difficulty constantly ignored as to the adaptation of new plans to old buildings. It is all very well to talk of providing a separate flue for carrying off the vitiated air, but becomes an expensive task in the ordinary way, in building a new house this can be done at very little expense or trouble; it is, therefore, a relief to be told that in old buildings, in addition to which the 'sua modo' is more likely to be effective in result. Be it said that these handbooks are intended for a practical audience and to remove erroneous impressions must expect reference to known facts, and we are reminded to be reminded that fogs must from their nature constantly recur. It is a highly popular belief that they are peculiar to London, but we have known them of the atmosphere in Paris and elsewhere, not so thick black to be sure, but accompanied with a coldness paralleled intensity.

'Fog appears to be formed by the condensation of aqueous vapour in the atmosphere upon any solid which may be at hand. The formation of fog, therefore, depends in the first place upon the presence of aqueous vapour, and in the next place upon the dust particles in the atmosphere. If there were no dust there would be no fog or rain, but the aqueous vapour would condense upon the trees or houses or our clothes. Fog, therefore, only is produced when there is abundant dust nuclei and plenty of vapour, and we find ammonia (which exists largely in connection with life) and the products of combustion of the sulphur coal, appear to have a similar affinity for vapour.'

'It is thus evident that all fires, however perfect combustion, are fog-producers when accompanied by certain conditions of moisture and temperature, and combustion, under all conditions, is bad as a fog-producer. It is hopeless then to expect that by adopting fires of perfect combustion—such as gas fires, now so much advocated—we would thereby diminish the fogs which presently envelope our towns.'

es Captain Galton point a moral and adorn a tale
an two cities. Prevention, we know, is better
but, being unable to prevent, suggestions are
he amelioration of existing conditions, and the
mployed are clearly defined by ample illustra-
figures.

fort the open fireplace is not to be denied, and

Hints on House Drainage. By a Clerk of Works.
London: Boot & Son.

r of this pamphlet starts with the assertion that
inage is a matter which does not generally re-
ient attention from builders and others to whom
nary to entrust this important branch of house
n, there being often a lamentable lack of super-
: the laying and fixing of these indispensable
s and traps.' As affecting the ordinary builder
oubtedly only too true; but these remarks can
said to apply to the 'others' who carry out this
when the arrangement of the drainage is taken
builder's hands, it implies that it is undertaken
ent sanitarians or sanitary engineers, and then
be carried out almost too carefully to suit the
the average householder, as in the concluding
as it is stated that simplicity, combined with
manship and materials, should be studied in
to any complicated arrangements, which often
re attention to keep them in order than they are
to get. There is a good deal of truth in this
ent, and it behoves the owner to adopt, if pos-
se as simple as is consistent with safety, as in
e work should not be allowed to get out of
use no one else about the place can understand
d wherefore. Attention is also called to the
water-traps, though eminently useful, must not
pon by themselves to keep back sewer-gas, and
nents and tests from 'Blackie's Encyclopædia'
to prove the affinity of such gases for water.
it needless to say that ventilation of the pipes

and traps is recommended, so that the foul air can be dis-
persed as soon as generated. The fallacy of depending
upon disinfectants is likewise adverted to, for, although
they are useful in their way, they are, with some excep-
tions, more likely to disguise than to destroy. To
sprinkle chloride of lime was formerly considered by the
general public to be sufficient to meet all sanitary require-
ments, or the occasional use of permanganate of potash
was supposed to be highly efficacious under all circum-
stances; it is, therefore, very necessary to point out that
such remedies are but partial.

These 'Hints,' so far as they go, are certainly sensible
and practical, but they are not sufficiently extended to be
of much use beyond suggesting a further inquiry on the
part of the unprofessional reader; for instance, the follow-
ing paragraph would not convey much idea to those with-
out sanitary knowledge. 'The outlet into sewer should
be provided with a proper tidal flap, and the length of
drain between the syphon and sewer ventilated.' These
generalities tend to arouse a further interest which is grow-
ing fast among all classes, and as such they are no doubt
useful, as when an interest is thus fairly awakened, there
is no lack of fully illustrated works to expound the subject
more clearly. The pamphlet concludes with a recom-
mendation that a complete plan of all drains and their
connections should be attached to the title-deeds of every
house. This is a point too often neglected, and the omis-
sion of so doing is the more to be reprobated when
the great saving of eventual trouble and expense is taken
into account. In most houses of importance there is
usually a coachman or gardener who has an intelligent
knowledge of the way the house-drains run, but, failing this
source of information, it often becomes a matter of serious
consideration how to trace the various courses. It is
always advisable to have a properly prepared plan of the
system mounted and varnished and hung up for reference
in an easily accessible place; the trouble is not much in
the first instance, and, sooner or later, is of great advan-
tage.

*Hygiene: its Scope, its Progress, and its Leading Aims,
and Health and Social Science.* Two Addresses deliv-
ered before the American Public Health Association
by the President, EZRA HUNT, M.D., M.A., D.Sc.

If translated into vernacular English, one might find
some instruction in these pages, or at least matter for
reflection as to the spirit in which the study of hygiene
should be pursued, the dangers of one-sided speculation,
or the premature popularisation of scientific hypotheses,
and the perversity of public bodies willing enough to
spend money in endeavours to repress epidemics, but nig-
gard in their expenditure for their prevention or for the
furtherance of research.

But to wade through page after page of inflated and
stilted expressions, of sentences that take away one's
breath, and words the meaning of which one has to guess,
though endurable in authors of undoubted genius, as Car-
lyle and Emerson, is extremely wearisome in their feeble
imitators.

The almost invariable misspelling of French and German
names, and of words derived from Greek and Latin, which
we have frequently had to animadvert on in American
literature, suggests unfavourable reflections as to the in-
trinsic value of the degrees in arts, medicine, and science
(for a wonder a professor and editor is not also LL.D.)
which Dr. Hunt appends to his name.

One sentence, by no means an extreme example, but
selected as a complete whole, may serve to illustrate the
author's style:—'So sure as the reign of law is the grand
fidelity and constancy that pervades the universe of God,
and forms the nexus of which all human law, called
government, is but a copy or an attribute, so sure is it that
we must find out and follow out in the individual and
social life those laws of health which pertain to the com-
pact not less than to the individual.'

Elementary Physiology adapted to the Syllabus of the Education Department. By G. T. HETTANY, M.A. (Cant.), B.Sc. (Lond.). London and Derby: Bemrose & Sons. 1900, pp. 160.

THE introduction of physiology as a 'specific subject' into the curriculum of elementary schools is calculated to be of no small value to teachers and pupils, and the knowledge thus acquired is of at least as great practical importance as that of physical geography or political economy. But the difficulty has been to divest the teaching of technicalities and to bring it really within the comprehension of children of average intelligence. As a small work on physiology Huxley's is perfect, but it requires, if not a scientific education, at least a degree of mental training and intelligence which we cannot expect to find in the ordinary boy. Mr. Bettany has completely overcome the difficulty, and produced the only book on physiology which is quite within the comprehension of children and yet is sound and trustworthy and free from everything like 'twaddle.' Following English usage he devotes at least half the work to what Germans would call anatomy rather than physiology, and since his physiology is professedly elementary he does not enter into such questions as metabolism and the production of heat and force, or the higher phenomena of the nervous system, as inhibition and the controlling functions of the cerebral centres. But so far as he goes his work leaves nothing to be desired on the score of scientific accuracy or simplicity of language, and each chapter is followed by questions and illustrations or experiments, not of the nature of vivisection, but enough to give a practical character to the teaching.

Hygiene: a Manual of Personal and Public Health. By ARTHUR NEWSHOLME, M.D. (Lond.) Pp. 400.

Hygiene, or the Principles of Health. By JOHN PILLEY, F.C.S. Pp. 174. Geo. Gill & Co., Warwick Lane.

THE recent addition of hygiene to the list of subjects in which examinations are held and certificates are given by the Science and Art Department has led, and will doubtless for some time lead to the production of a number of text-books of various degrees of merit. Dr. Newsholme's is by far the best we have yet seen; the author's degree is a guarantee of the extent and accuracy of his scientific and medical knowledge, but he has the gift of expressing himself in clear, concise, and at the same time attractive language; indeed, we are really surprised at the mass of facts and information he has succeeded in compressing into the limit of a very modest volume. We cannot, however, help thinking that, in common with all writers on dietetics, he places too much reliance on the estimates of potential energy contained in different foods, founded on the chemical theories of Playfair and Frankland, but recently called in question by the Munich School of Physiologists. Metabolism is not identical with combustion; it is oxidation, but oxidation accompanied by complex and diverse collateral phenomena of splitting up, combination, and storage in the organism, besides being mostly incomplete. We much doubt whether the value of fat is so much higher than that of the carbohydrates as Frankland teaches; in fact, we believe that it is nearer $1\frac{1}{2}$ than $2\frac{1}{2}$ to 1.

Again there is abundant and positive evidence of the direct conversion of proteids into fat, simultaneously with the metabolism of the other moiety into urea, whereas considerable doubt has been thrown on the formation of fat from non-nitrogenous food-stuffs, which may rather lead indirectly to its formation from the proteids. Too little is known of the vital processes in insects to justify referring, as Dr. Newsholme does, to Milne Edwards's observations on bees; while the example of the Strasburg geese rather supports the proteid view, since their fat is obviously derived mainly, if not wholly, from diminished oxidation and fatty degeneration of the nitrogenous tissues.

Dr. Newsholme, following Blondan, quotes the

'ripening' of cheese as an instance of the conversion of albumen into fat; this view is certainly erroneous; change takes place only in the living organism; increased percentage of fat is due, as Alex. & Sieber have shown, to the loss of water, and is, apparently not real.

His statement that barley and maize contain *gluten* is likely to be misunderstood; he no doubt means what he elsewhere calls *glutia*, viz., vegetable mucosin of some chemists, which gives to wheat and rye-flour the tenacity that renders them capable of being made into bread.

The chapter on the prevention of infectious diseases is admirable; the author rightly describes cow-pox, modified by passage through the bovine, and not as the French school still maintain, as evidence to the contrary, as a spontaneous animal disease; but he is, perhaps, too sanguine as to the application of the 'cultivation' theory in the signal failure of Pasteur's 'vaccines' where and they have been tried by others - even by his countrymen abroad.

The book, however, is excellent as a whole, as regards the amount of information, the detail and absence of padding of any kind, the consistency of the author's views on every subject, and the elegant almost may elegance, of his style.

Though not so described on the title-page, from the contents that Mr. Pilley's book is intended to meet the requirements of candidates in elementary stage. The physiology is not, however, present state of our knowledge. Thus nitrogen is everywhere described as flesh-forming, tissue-forming, and so forth, but there is not the remotest allusion to their influence in accelerating metabolism with Pottenkofer and Voit among others have shown them, if in relative excess, tissue wasters; and what principle on which Bantingism is based. Nor does Pilley refer anywhere to the indisputable production of proteids which rests on clearer experimental evidence than the direct conversion of carbohydrate into fat.

Speaking of lime salts Mr. Pilley says, 'When given to young children is deficient in these salts rickets frequently result.' Whereas, though the bones may be deficient in earthy matter there is no evidence that the disease is ever produced in it; it is improper feeding, no doubt, in most cases the cause, but quite irrespective of the amount of lime, remedy is so useful as cod-liver oil, which improves nutrition, though certainly not from containing lime.

Mr. Pilley commits himself to a sweeping condemnation of condensed milk for infants as inferior to pure milk to the comparatively small quantity (?) of saline matter. A somewhat extensive experience has satisfied us that very young infants, at any rate, thrive as well on better on condensed than on fresh cows' milk; besides the fact that the latter is as deficient in sugar as the former is the reverse, the casein in the condensed is easily digested than it is in the fresh, and the whey, like that of asses' versus cows' milk, is one of the capability of assimilation than of chemical composition.

The carbonic acid in water, in virtue of which it solves calcium carbonate, is repeatedly stated to be from the air. As a matter of fact the quantity of carbonic acid by rain is extremely small, certainly less than 0.006 of its volume. The great source of the spring water is the ground air, the existence of which Pilley ignores altogether, which contains never less than 6, or 8 per cent. of its volume, and may contain as 20 or 30 per cent., while the atmosphere has but 0.03 per cent. The sanitary bearings of this fact are of the greatest importance.

In the chapter on parasites the author refers to reports of fatal trichinosis from eating American pork, and the recent prohibition of its importation into France.

mentioning the protests of all the leaders of the medical profession in that country on the ground that no such cases ever been heard of; an opinion likewise expressed by highest authorities in Germany, the trichinae in American pork being always dead or nearly so. Every German emic has been caused by the consumption of home-fed, raw or half cooked; the same is true of Sweden and Asia; indeed the only instance in this country was caused by the imperfectly cooked flesh of a pig born and in Cheshire.

NEW INVENTIONS.

VERY CHEAP VENTILATION FOR WORKMEN'S HOUSES, INDUSTRIAL DWELLINGS, &c.

an automatic exhaust roof ventilator, 10 inches in diameter, with an 8-inch shaft, on Stafford's principle, provisional specification No. 3,216, October 21, 1863, which is free from down draught as any automatic ventilator of this class, and possesses the advantage of carrying a shaft

case by openings 4 inches in diameter in the angles of the first-floor rooms at the points marked D D. From the junction of C C the main shaft divides into two 4-inch shafts E E, which penetrate the ceiling in the angle of the first-floor room, but inside the outlet D. This angle is closed in from the ceiling to the floor below by a 7-inch board, or a strip of galvanised iron, let into the wall on either side F F, thus forming a continuous shaft from the 4-inch G.I. pipe E E, and is connected through the floor and ceiling at point G G with the ground-floor rooms. This provides for a simple system of outlet, all the shafts of which are vertical, or nearly so, and thereby avoids the condensation and tendency to back draught inevitable with horizontal pipes, or pipes having only a slight rise. H H H are four inlet brackets, 11 inch by 6 inch by 2 inch. These inlets are fixed at the opposite side of the rooms to which the outlets C and G are fixed. The *Æolus Waterspray General Ventilating Company*, 225 High Holborn, W.C., supply the above—viz., one 10-inch Stafford's exhaust roof ventilator, with 8-inch pipe, two 4-inch branches, one double 4-inch branch, four 10 feet lengths of 4-inch by 7-inch matchboarding or galvanised

—SECTION THROUGH HOUSE—

only as large as the head, the extracting power of any properly constructed roof ventilator lying in the diameter of the shaft which it is able to carry, and not in the size of the head. H is the 8-inch main shaft, which descends to 2 feet of the ceiling of the upper room, and there divides the two 4-inch outlet pipes C C, which communi-

cate by openings 4 inches in diameter in the angles of the first-floor rooms at the points marked D D. From the junction of C C the main shaft divides into two 4-inch shafts E E, which penetrate the ceiling in the angle of the first-floor room, but inside the outlet D. This angle is closed in from the ceiling to the floor below by a 7-inch board, or a strip of galvanised iron, let into the wall on either side F F, thus forming a continuous shaft from the 4-inch G.I. pipe E E, and is connected through the floor and ceiling at point G G with the ground-floor rooms. This provides for a simple system of outlet, all the shafts of which are vertical, or nearly so, and thereby avoids the condensation and tendency to back draught inevitable with horizontal pipes, or pipes having only a slight rise. H H H are four inlet brackets, 11 inch by 6 inch by 2 inch. These inlets are fixed at the opposite side of the rooms to which the outlets C and G are fixed. The *Æolus Waterspray General Ventilating Company*, 225 High Holborn, W.C., supply the above—viz., one 10-inch Stafford's exhaust roof ventilator, with 8-inch pipe, two 4-inch branches, one double 4-inch branch, four 10 feet lengths of 4-inch by 7-inch matchboarding or galvanised

PATENT SLOP-STONE WASTE-PIPE PROTECTOR.

THIS is a small, cheap, and useful invention, intended to obviate the unsightly lead or other pipe protruding through the wall from the sink, and to regulate the flow of the water to the grid, and prevent splashing, or the water getting into the foundation of the wall. It consists, as the accompanying drawing will show, of a salt-glazed fire-clay block, 12 inches long, 6 inches broad, and $4\frac{1}{2}$ inches thick, of which A and B in the small illustrations are the front and back views. C shows the block built into the wall, behind which is the sink or slop-stone E. The waste-pipe from this is passed through the wall in the usual way, and inserted about 2 inches into the hole, as shown on B, and the water then runs on to the dished grid D. Although

any shaped grid will of course answer the purpose, the one devised by the inventor of the protector, and shown in the illustration, is of excellent design, is made in two sizes, and enables the gully to be placed at least 18 inches from the wall, enabling the recommendation of the Local Government Board to be complied with, and preventing any smell that may arise from the gully passing back into the house through the slop-stone pipe. Besides making the arrangements for carrying off waste water complete, and rendering the surroundings neater and more cleanly, it saves one foot of lead pipe in each case where it is used, and prevents any damage to or incentive to steal it. The protectors are being extensively used in the Lancashire district, and only require to be generally known to be largely adopted, their very small cost being an additional recommendation. Further information can be obtained of the proprietors, Messrs. T. Griffiths & Son, builders' merchants, 84 Chorlton Road, Manchester.

GIBBS'S CONCENTRATED CARBOLATED CREOSOTE.

THIS is a cheap and valuable disinfectant, introduced by Messrs. D. & W. Gibbs, of the City Soap Works, E.C., and Abbey Chemical Works, Stratford, E. It is a mixture of carbolic acid and other disinfecting bodies, equally powerful as antiseptics, with the addition of the oils of creosote. It probably contains more disinfectants in its composition than any other compound of the kind now in use, is as efficacious as the most costly, is more agreeable, not so dangerous as carbolic acid when used alone, and costs less than 2d. per gallon. Apart from the ordinary disinfecting uses, a small quantity (about a tablespoonful) added to the bath will be found very refreshing, and mixed with the water in a laundry in the proportion of a half-pint to 25 gallons of water, its beneficial effects will soon be experienced. It will be found equally useful in the washing of dogs, and for stables, &c. A small quantity of this disinfectant, mixed with a pail of water occasionally thrown into the dustbin will render it harmless, though the refuse should of course be removed at frequent intervals. The advantages of creosote as a preserver of wood is well known, and the carbolated creosote may be used with advantage as a disinfectant and

preserver, mixed with water and used as a paint for covering walls, woodwork, &c., before papering. Professor Attfield speaks of it in high terms; so also does Dr. Cameron, F.R.C.S.I., as a 'most powerful sanitary agent.' It has been extensively used during the recent hot weather for the deodorising of the London sewers, and Dr. Sedgwick Saunders, the Medical Officer of Health for the City of London, strongly recommends it.

A HANDY SULPHUR FUMIGATOR.

MR. T. SIMPSON, the Sanitary Inspector of Hillhead, Glasgow, has invented a new Sulphur Burner and Fumigator, a drawing of which is appended. Outside measurements, 8 inches in diameter and 5 inches deep. It consists

of two copper vessels, cylindrical in form, the one set inside the other, leaving about an inch of space between the sides and three inches between the bottoms. The inner one can be removed at pleasure for the purpose of placing the sulphur in it, or for extracting the water which is placed in the outer one; to the top of the inner one is fixed the gas pipe, the coupling of which acts as a handle for lifting it in or out, and which fits into a notch in the outer shell. When in use, the outer one is filled with water as shown in drawing, and the sulphur in the inner one, the flame from the gas striking the sulphur and keeping it alive, at the same time heating the water and causing it to evaporate rendering the atmosphere of the room moist and thereby completing the disinfection, and the water, in said outer shell, preventing any danger of fire in the apartment. The cover is for placing on it when carrying it from place to place. The apparatus may be had from Messrs. Reid & Co., Plumbers and Sanitary Engineers, Byars Road, Hillhead, Glasgow. Mr. Simpson has had this apparatus in use for four years and finds it very satisfactory, and it was exhibited and highly commended at the meeting of the Sanitary Association of Scotland held at Perth on the 20th ult.

CAMPBELL & CO.'S SANITARY FLAKE CHARCOAL.

AMONGST the deodorisers and disinfectants now at command, the Flake Charcoal manufactured by Messrs. Campbell & Co., Cartvale Chemical Works, Paisley, deserves recognition. The value of charcoal as a deodoriser is a recognised fact, and if it could be produced in sufficient quantities and at a price that would enable local boards and other authorities to use it indiscriminately, it would be a very great boon. That consummation is at the present time impossible, but there are some districts more favoured than others, and the one around Messrs. Campbell's works is a case in point; where through the influence of Dr. Richmond, the Medical Officer of Health of Paisley, the flake charcoal is in indiscriminate use all over the district for dry closets, cesspools, middens, and decaying matter. Messrs. Campbell, who are extensive chemical manufacturers, produce this valuable disinfectant in large quantities from one of their residuums. It is made from birch wood chips and shavings free from bark, being the residue from the destructive distillation of these substances in the patent retorts used by the firm. The charcoal weighs only 10 lbs. to the cubic foot, and, though bulky, lies close. It is sold in bags containing about five bushels,

and delivered in Glasgow and surrounding neighbourhoods about the same distance at 2s. per bag, at which price it may reasonably be considered that it may be used without stint. It is to be presumed that as Messrs. Campbell can afford to sell it at such a low price they can produce it in large quantities. All that is required in using it is to cover entirely the matter to be deodorised, a depth of about two inches being preferable, when no fear need be felt in reference to the most putrid matter. For dry closets and middens, less than half this depth is sufficient. The writer has made an experiment with it on a dead rat rather far 'gone,' with the most satisfactory results. As chemical works abound in many districts, perhaps some other firms who use wood in the same manner as Messrs. Campbell will be induced to try the experiment, and so benefit their neighbourhoods, and utilise what may be assumed to be an almost useless residuum. The firm will deliver this charcoal F.O.R. London at the price quoted in 4-ton lots, bags included, about 40 to the ton.

A NEW 'CUT-OFF.'

MR. WILLIAM GRAY, M.R.I.A., District Officer of Public Works, Belfast, exhibited at the meeting of the Medical Association in August what he terms a 'cut-off,' by means of which any residence or other premises can be effectively 'cut off' or disconnected from the town or main sewers, so as to prevent the return of sewer-gas. Several plans have been devised for this purpose, from which Mr. Gray's 'cut-off' differs only in being more simple in construction and effective in operation, while at the same time it renders

the house drainage accessible for examination at all times, so that the householder can see for himself that the drains are in proper order. The 'cut-off' is formed of terra-cotta, and consists of a dished open chamber or air space through which all the house sewage must pass, and from which it is conducted rapidly by a syphon trap into the town sewer. The foot of soil-pipe enters this chamber, and with the vent pipe at top promotes a constant current of fresh air through the soil-pipe, while the sewer-gas is completely excluded.

A NEW GREASE TRAP.

MR. S. COWAN, joiner to W. H. Maxwell, Esq., of Munches, Dalbeattie, N.B., sends us a sketch, as under, of a grease trap, for which he has taken provisional protection, and intends exhibiting at Dublin, on the Exhibition of the Sanitary Institute, to be held in October next. He formerly found a grease trap at Munches, which was placed about 60 feet from the scullery sink. The interior of this

trap formed a perfect cube of 2 feet each way, with a bend into it, the outlet being some 6 inches below the water. The wastes there ran through another trap of the same dimensions, with inlet and outlet from the surface of the water. The outfall drain from this last chamber was a 4-inch ordinary drain tile, and in three years the whole got completely stopped up with grease.

A few months ago he devised the above trap, which is built in brickwork, with bends at each end, by means of 4-inch fireclay material, and he fixed on the top a concrete frame with 2-inch iron lid, and placed outside of wall from scullery sink, and recommends a 3-inch air pipe from trap, where it can be carried out, to carry off steam, &c. His intention is to have them altogether made of fireclay. The main feature of this trap is the distance the water has to flow before leaving the trap, and by this plan the water gets thoroughly cooled and the grease floats to the surface.

THE 'BEE-HIVE' REFUSE DESTROYER.

A NEW furnace for the destruction of town's refuse has recently been invented by J. E. Stafford, Esq., A.M.I.C.E., the Borough Engineer of Burnley, which promises to be extensively adopted. The scavenging in the town of Burnley during the past five years has cost on an average 1,500l. per annum. This cost will be considerably reduced in consequence of the erection of this Destructor, which will consume a large amount of the sweepings, &c., which previously had to be carted some considerable distance to several depôts in the town, and afterwards disposed of to farmers and others at an average price of 4s. per cartload. Great complaints were raised by the public, especially in summer, of the objectionable smells which arose from the matter deposited at these depôts, and no doubt the medical officer of health was perfectly justified in condemning these depôts as detrimental to the health of the public. The expense incurred in the labour required in stacking up, and keeping a check on the carts owned by persons who purchased this matter, also the cost of disinfecting the same, was not by a considerable sum balanced by the revenue derived from it, as during the last five years the average sum derived on this account was 50l. per annum, and the expenditure in men's wages alone was 54l. 12s. After the depôts had been condemned, the matter was disposed of by water-carriage, but this arrange-

ment obviated but slightly what had previously occurred, the boats having, of course, to stand at the canal bank until they were loaded, and giving, as before, great cause of complaint about the nuisance arising therefrom. The Destructor recently erected is working most successfully, and gives the greatest satisfaction to the public. All descriptions of the most objectionable matter produced by the town, such as offal from slaughter-houses and fishmongers' shops, garbage, ashpit contents, street sweepings, &c., are being effectually destroyed without smell or residue, and a considerable saving in the expense of carting the sweepings has been made in consequence of the convenient position in which the Destructor is placed. This the writer saw about a fortnight since, under the guidance of Mr. Stafford, the inventor, and Mr. Birtwistle, of Burnley, the maker, and was very much struck with the heterogeneous character of the matter that had to be dealt with. The rapidity with which the Destructor disposed of it was remarkable, and although inspected during the very hottest weather, not the slightest unpleasantness was apparent; in fact, the effective manner in which it accomplished its work left no doubt on his mind as to the value of the invention. Two illustrations of it are appended, fig. 1 being a front, and fig. 2 a side elevation, by which it will be observed that it is only 7 ft. high, and the same size in diameter. A is the feed hole for refuse, running to and fro on rollers, and nearly on the level of

thoroughly established, numerous inquiries have been made and deputations from other towns have visited Burnley to see its effects; it is stated that in every case the visit has resulted in an order being given for one or more. Amongst these deputations one from the Vestry of Richmond, Surrey, who had heard of the success of the Destructor, were induced of their own accord to pay a visit to Burnley, and the result was that the vestry decided to have two erected for ridding themselves of a nuisance that has become a matter of momentous import to all localities where large bodies of people reside.

It is certainly very creditable to the public spirit of this charming Thames-side town that it has been the first in the metropolitan district to adopt the Destructor, which was visited by the writer on September 2. There being no chimney-stack at Richmond, it became necessary to erect one, which has been built in the Corporation Yard near to New Richmond. Here a handsome stack has been built by Messrs. T. Birtwistle & Co., of Burnley, some ninety feet high; and the greater part of the bricks used in its construction have been sent by rail from Burnley, as the London-made bricks were utterly repudiated by Mr. Birtwistle and Mr. Lomas, the London agent. The Burnley bricks are of superior make, and specially suited for the purpose of building stacks. The chimney is built square at the base, and at opposite ends of the two parts of the square a Destructor is erected, a 'mal-

platform where the refuse is shot; B, feed hole for fuel; C, peep holes; D, air holes; E, wrought iron bands, carried round circumference; F, water hearth. It is made entirely of fire-clay bricks of the finest quality, and presuming that a chimney stack exists (as it did at Burnley) wherever the Destructor is erected the entire cost amounts to about 100*l*. The one in question is destroying on an average twenty-four loads per day of about 19 cwt. each, and the writer was assured that the entire cost (labour of all kinds included) does not exceed 10*l*. per load. The residuum, which is remarkably small, falls into a water tank underneath, where it is quickly cooled, and the steam evaporated from this water tends to keep the bars of the furnace cool. According to the kind of matter being burnt, so is the residuum, and the lighter kind is so fine that it can be utilised for mixing with mortar, while the heavier, which takes the form of clinkers, makes good material for the underlying or bedding for roads, and it is not improbable that, all things considered, the cost of scavenging in the town of Burnley will eventually be reduced to almost nil. Mr. Stafford's idea is that by erecting Destructors in different neighbourhoods, each locality will be enabled to get rid of its own productions. Cartage to a central spot will be dispensed with, and the inhabitants of different districts will not be annoyed by the smells arising from the garbage being transported through a long line of streets.

Since the success of the Beehive Destructor has been

'feather' in the chimney securing an independent flue for each; and arrangements have been made in building the stack for two more Destructors to be erected on the other sides of the square. The entire cost of the stack and two Destructors has been 450*l*., while the other two can be set up when required at an expense of about 100*l*. each. Although only just set to work, the employees at Richmond appear to understand the value of the Destructors, and are working with a will at them. A few weeks' experience will doubtless convince the inhabitants of the value of the step taken by their authorities. The remarks as to the class of matter being burnt at Burnley apply equally to Richmond, where the dustbins appear to be receptacles for everything that enters the house, animal, vegetable, and mineral, manufactured and unmanufactured.

The work done at Richmond by Messrs. Birtwistle is not a profitable undertaking, in consequence of the desire of the firm to make the work a pattern for the London district; their estimate was also based on the supposition that bricks could be purchased in the neighbourhood suitable for their undertaking; but, as events turned out, nearly all had to be sent from Burnley—to their loss, but to the gain of the Richmond authorities. Mr. Lomas (who has acted throughout as Messrs. Birtwistle's agent, and is a retired Burnley manufacturer) has taken up the matter as much from a desire to assist his townsmen as from any desire of gain, and he is to be complimented on the

Yet 'X. Y. Z.' claims Dr. Collie as in agreement with him in contending that in the crowded and ill-ventilated dwellings of the poor, deficient in every way for the safe treatment of a communicable disease, with the sick and the healthy sleeping as they must do within a few inches of each other, typhoid patients can be safely treated without danger to the health of the remaining inmates, that in fact what cannot be done, as is proved, in the airy and spacious wards of well-appointed hospitals without grave danger, may be safely done in crowded cottages, with no skilled nursing, bad ventilation, and inadequate breathing space.

The whole tenor of Dr. Collie's article was opposed to such an assumption as this. I believe the doctrine held by 'Dilemma' that it may possibly be 'advisable' to remove typhoid patients to a fever hospital, but never 'necessary' to do so is fraught with danger to public health, and on that account I have protested and shall continue to protest against it.

As to the other matters referred to in your correspondent's letter they are purely personal and may well be passed over; but, at any rate, it will suffice for me to reaffirm my first statement of particulars.

August 23, 1884.

M. S. E.

CHEAP DINNERS FOR DESTITUTE BOARD SCHOOL CHILDREN.

THE Committee of Representative Managers of London Board Schools have sent us a circular from the sub-committee appointed to consider the subject of cheap dinners for destitute scholars. It deals with a pressing and difficult question in a very practical way.

The circular states that in several of the Board Schools many children are unable to learn as much as they otherwise would from the fact that they are insufficiently fed. How to supply this want without pauperising the parents is a difficult problem, but from careful inquiry made by the sub-committee, they have ascertained that under certain conditions substantial and nutritious dinners can be provided at 1d. each to pay all expenses.

The following dinners have thus been supplied recently at certain Centres: Soup with bread and bread and jam; bacon sandwiches and bread and jam; jam roll-polly pudding; stewed meat; cold bacon and bread; hot bacon and beans; Irish stew; beef and macaroni; currant pudding; stewed meat and vegetables; rice with milk and treacle or sugar; bacon and hot potatoes; bread and cheese; bread and jam.

The conditions necessary to make such dinners self-supporting at 1d. each, are:—1. An average daily attendance of about 200 children, including those whose portions are purchased for home consumption. 2. Skilful organisation in buying and preparing the necessary food. 3. A suitable room, with one or two coppers available, in the neighbourhood of one or more Board Schools, which can be hired at a moderate rent. 4. A sum of about £10 for preliminary expenses.

As it is extremely desirable that efforts should be made in various localities to meet the need of under-fed scholars during the coming winter, the representative of each school or group of schools is earnestly requested by the Chairman of the Committee, R. J. Simpson, Esq., to bring the subject before his committee at the next meeting, and to be good enough to send replies to the following questions to H. Forbes Clarke, Esq., the hon. sec. of the sub-committee, as soon as possible. If only a few children in any school are in need of such help, the sub-committee will be glad to know, as a centre might be arranged for several schools in any given locality.

The questions to be replied to are—1. Are there any schools in your group for which such provision is necessary? If so, please name them. 2. About how many children in each school would be likely to purchase penny dinners daily? 3. Is there any suitable room available in your district? 4. Are there any managers or other local persons who are willing to provide or to help in providing such dinners?

Further information can be obtained of the Hon. Sec. of Sub-Committee, H. Forbes Clarke, Esq., Camden House, Hungerford Road, Holloway, N.

HOUSING OF THE WORKING CLASSES.

*'How best to help the slender store,
How mend the dwellings of the poor?'*

THE ROYAL COMMISSION.—The Government appear to have repented them of their determination expressed in Parliament some months ago by Sir Charles Dilke, not to add to the Royal Commission on the Homes of the Poor any members to represent Scotland and Ireland; for it has lately been announced that Sir George Harrison, the present Lord Provost of Edinburgh, and Mr. Dwyer Gray, M.P., a former Lord Mayor of Dublin, have been

added to the Commission. The former has evidently determined to justify his appointment forthwith; for we read that in company with Lord Carrington, who has developed quite a taste for 'slumming,' he made the other day a minute inspection of some of the worst quarters of the city over which he presides. The 'closes' of Edinburgh are historical, and perhaps on that account may safely be set down as dirty. The enormously high houses that are so conspicuous a feature of the city architecture have their own special sanitary lessons to teach; and we may hope for some useful result from the 'copious notes' that Lord Carrington is reported to have taken during his inspection.

A DISGRACEFUL case of overcrowding has been brought before the borough magistrates of Folkestone, on an application by the Town Council for an order to compel the occupiers of the house to abate the nuisance. It appeared from the evidence of Dr. Bateman, the medical officer of health, and the inspector of nuisances, that a small four-roomed cottage, with scullery and box-room, had been tenanted by no less than four families, comprising nineteen persons, the ages varying from old age to infancy. In addition to this there was no water supply to the house. The defendants complained of the want of cheaper and better occupations for the poorer classes. The magistrates made the necessary order, remarking that, according to the cubic capacity, not more than six persons should occupy the house.

THE *City Press* states that it is proposed to erect a block of artisans' dwellings in Chatham Gardens, City Road, at a cost not to exceed £50,000. The property, which is known as Bleyton's Gift, is vested in trustees selected from the parishes of St. Giles, Cripplegate, and St. Luke's, Old Street. The Charity Commissioners have approved generally of the scheme, and the details only remain to be settled.

A GRATIFYING account of the working of the Labourers' (Ireland) Act, 1883, is given in the report of the Irish Local Government Board just issued. By the end of the present year the Board estimate that they will have made orders confirming schemes by the sanitary authorities to provide over 2,800 labourers' dwellings with land attached thereto. In addition to this, however, it is reported that the Act has been indirectly the means of drawing attention to the defective sanitary state of labourers' dwellings in many localities where improvements have since been voluntarily effected by the owners.

PARKS AND OPEN SPACES.

*The law condemns both man and woman
Who steals the goose from off the common;
But lets the greater felon loose,
Who steals the common from the goose.*

THE PECKHAM RYE COMMONS.—Since the Metropolitan Board of Works took possession of these commons in the early part of last year, a series of improvements have been effected. These improvements are now nearly completed, and from the deplorable condition in which the commons were two years ago, they have been transformed into the most pleasant open spaces in South London. At the entrance to the Rye is a large open space, which, from its proximity to the main road, has by constant traffic been entirely denuded of grass for years past. This spot has been enclosed and a shrubbery planted, and a portion of the lower end of the Rye has also been partially enclosed. All the grass has been re-sown, and to prevent inconvenience to the public a small portion only of the common has been enclosed at one time. East Dulwich Green has been levelled and enclosed, and Nunhead Green has also been partially enclosed.

IN America the importance of country holidays for

lren seems to be more widely recognised than in

A report has recently been published of the : in 1883 in this direction, in connection with a : cted by the *New York Tribune*. The amount d last year was upwards of 3,000*l.*, and for this dren had the benefit of a fortnight's holiday in y, and 5,700 had a day trip.

just 20 the Prince of Wales formally opened the ; Park at Newcastle-on-Tyne amidst much ejoicing. At the same time the Princess of nted a tree as a memento of the occasion.

LAW REPORTS.

POLLUTING THE WATER SUPPLY.

LLIS appeared at the Police-court, Clerkenwell, a summons issued at the instance of the New mpany, under the Waterworks Clauses Act of ging that on Aug. 3 he washed, threw, or caused nto the New River, a certain dog. Evidence l to prove that the defendant's dog entered the ch was one of the sources of the water supply of polis. The defendant said he was surprised hould be prosecuted for so trivial an affair. re constantly sending their dogs into the river, tice was taken of it. Mr. Barstow said he did ler the offence trivial. It was a very dirty trick, her people were in the habit of doing it, he New River Company would take it up. He defendant 40*s.*, with 2*s.* cost.

TINNED TOMATOES.

for 50,000 dollars damages has been brought fessrs. Thurber, Whyland, & Co., grocers, of e City, by Miss Kolver, as compensation for jury done to her health through eating tomatoes cans by that firm. In her bill of complaint Miss tes that the tomatoes in question were labelled rior quality, and that her father was thereby n March 5 last, to purchase a number of cans rooklyn grocer. They were cooked and she ate ey proved poisonous, and she became so ill ife for a time was despaired of and her health ly injured, all of which entailed heavy doctors' adds that the cans were soldered with poisonous s, which, falling into the cans, poisoned their

The suit is based on an examination of the case, made by Dr. Bartley, of the Health nt, who reported that the symptoms were those uld be caused by poisoning from muriate of as is used in soldering the cans. Eight similar awaiting the result of Miss Kolver's action.

THE ABATEMENT OF NUISANCES.

of some importance to sanitary authorities was Sept. 5 before the Melksham Petty Sessions, opes, Heathcote, and Stancomb being the sitting

elksham Rural Sanitary Authority summoned atson for non-compliance with their order to ertain serious sanitary defects in a cottage of was the owner. It appeared from the evidence lackenzie, the inspector of nuisances, and Dr. medical officer of health, that the water supply minated with sewage which soaked from a large iguous to the living-room of the cottage. These lvised that a supply of water should be obtained Trowbridge Water Company, which passed the at the pool should be cleansed from all sewage id thereafter filled in; and that a proper drain e constructed of glazed socketed pipes. The nal printed notices were served upon the owner. t refused to lay on a supply of water, and the authority had the work executed in terms of Public Health Act, 1875. On being threatened

with a summons, defendant filled up the pool with gravel, but did not remove the sewage matter. He also made a drain, but used agricultural pipes in its construction. The sanitary authority did not consider this a satisfactory abatement of the nuisance, and directed their inspector to write to defendant stating that proceedings would be taken against him. For the defendant, Dr. Grose, of Melksham, sent a written statement, stating that he had inspected the premises, and considered their sanitary condition to be most satisfactory. The magistrates, after consultation, dismissed the case, on the grounds that the sanitary authority ought to have sent a second formal printed notice to defendant after resolving to take legal proceedings. The magistrates who tried the case are all *ex-officio* members of the prosecuting sanitary authority. It should be stated that a case of enteric fever broke out in the cottage complained of.

CREMATION NOTES.

THE crematory now building by the United States Cremation Society is in a forward state, and it is stated that several dead bodies are already in waiting for its completion in November. It is situated in East Williamsburg, New York, between two cemeteries. The structure is 74 feet long by 40 feet wide, and in design resembles a Greek temple, with façade and return walls ornamented with Corinthian columns. It is to be the latest improvement in crematories. One novelty will be dispatch. The body will be placed in a catafalque in the chapel, a curtain concealing it from view. During the services it will sink to the furnace without noise, and when the services are ended, an urn will be found in the catafalque containing the ashes. There will be no intimation that anything is going on but the services for the dead.

The body of an Indian gentleman has been cremated at Etretat. Baboo Sahed Chatjay, who had accompanied his son-in-law, Sampatras, the brother of the Maharajah Guicowar of Baroda, one of the chief princes of India, to Europe, died recently at Etretat of an abscess in the throat. Permission having been granted by the Mayor to cremate the body, at midnight wood was carted down to the beach, behind a jutting point in the cliff, hidden from the town, and there a pile of two or three feet in height was carefully built of logs crossed and recrossed, with the ends towards the north and south. The ceremony of sprinkling the sacred powder over the body and anointing it was very simple. An eye-witness, writing to *Galignani's Messenger*, describes the ceremony as follows: 'The fire was in a small earthen bowl, and was made of sandal-wood, which is difficult to obtain in Etretat. But in this case a carved box, a *souvenir* of India, was presented for the purpose to the mourners by an English lady, who happened to have it with her. The body was laid upon the pile, with the head towards the north, and then covered with more wood saturated with oil. It was now two o'clock, and the funeral pile was carefully built. The Prince Sampatras threw the burning incense in the bowl upon the north end of the pile, which instantly caught fire, and speedily the whole mass was wrapped in flames. In an hour they began to subside, and more wood was piled on. Gradually the morning dawned upon the ceremony. The wind had blown away most of the cinders, and among those remaining only a few pieces of bone, keeping their form, could be found, and those crumbled when they were touched. What human ashes could be distinguished were gathered up, a part being thrown into the sea, and the rest sealed up to be sent to India. By six o'clock every vestige of the cremation had disappeared. When the rumour reached the awakened inhabitants of Etretat, and brought them in crowds to the spot, they hardly believed what was told them, for they only saw a few blackened stones and a few loose shavings that had escaped from the burning.'

SANITARY JOTTINGS.

SANITARY.

THE operations of the Sanitas Company for the past half-year have resulted in a large increase of profit as compared with the corresponding period of last year; and the directors have, in consequence, declared an interim dividend for the half-year ended June 30 last at the rate of 10 per cent. per annum, payable now. The directors add that the business of the company is increasing satisfactorily.

It would seem that the evils arising from the undue consumption of alcoholic drinks attracted attention in this country some centuries since. Mr. Jennett Humphreys, of Cricklewood, sends the following lines, written in 1656, but which are equally applicable to the condition of affairs at the present day, to a daily contemporary.

'The Drunkard's Prospective, or Burning Glasse.
' Composed by Joseph Rigbie, Gentleman, Clerke of the Peace of the County Palatine of Lancaster.
' London: Printed for the Author, and are to be sold at the Brazen Serpent in St. Paul's Churchyard, 1656.'
' Drink beaстиates the heart and spoiles the brains,
Exiles all reason, all good graces staines,
Infatuates judgement, understanding blinds,
Perverts the wits, and doth corrupt the minds.
It doth surprize the thoughts, and it doth all
The powers and faculties of soule enthrall.

' Drunkards for nothing that is good are fit,
In all the world of earth, the baren'st bit.
Like to a dumb Jack in a virginall,
They have no voice in commonwealth at all.
They've no more use of them throughout the land
Than Jeroboam had of his withered hand.

' Health out o' th' body, wit out of the head,
Strength out o' th' joints, and every one to bed.
All moneys out a purse; drink out o' th' barrels,
Wife, children, out of doors, all into quarrels.

' To you churchwardens, constables, and others,
That love the Lord, the Church, the State, your brothers,
Your selves, your sons, the people of the land,
Put forth against this sin your helping hand.
Help, help the Lord, the lawes, some ground to win,
Against I say, against this mighty sinne.'

WATER SUPPLY.

WATER SUPPLY OF NEWMARKET.—New waterworks have just been inaugurated at Newmarket. The works consist of a well and pumping station at South Field, in the parish of Exning, and they are designed to be capable of supplying 100,000 gallons in twelve hours. The pumping-engine is of the horizontal condensing type, and the pumps are of three-throw description, one set drawing from the well and delivering into the softening tanks, the other drawing from the tanks and delivering into a reservoir situate on Warren Hill, at a height of about 200 feet above the main street of the town, with the capacity of holding about 250,000 gallons. The works are being adapted to allow of the use of Clark's softening process, which has the effect of reducing the hardness to about four degrees. The shaft of the well from which the water is drawn is 20 feet deep, having two bore holes of 18 inches each, and each 40 feet deep. The works are arranged to admit of duplication of the machinery should it become necessary, and at present the engine is capable of pumping 400 gallons per minute. The water pumped from the well is conducted into two large tanks in the rear of the pumping station, from which it is conducted to the reservoir at the other end of the town. Each tank is capable of containing 100,000 gallons, and adjoining these tanks is a smaller one, used for the preparation of lime water for mixing with the water newly

pumped from the well. The water newly pumped and for the purpose of softening it a flow of lime a proportion of one to ten is continued. Each tank is fitted with a suction float adopted for the with surface water only. The whole length of piping the company, including the mains, is estimated at nine miles. The well was sunk at South Field September 1883, and the works were commenced beginning of December. The estimated yield of is equal to twice the present requirements of the town. The total cost of the works—somewhat increased by the necessity of applying to Parliament on two occasions—has amounted to 14,000*l*. The works were designed by Messrs. Easton & Co., of 11 Delabury Street, West. The machinery was erected by Messrs. S. S. Stott of Haslingden, near Manchester; and the boiler including the reservoir on Warren Hill, were carried by a local firm, Messrs. Hook and Tetbut, of Messrs. J. Young & Co., of Hertford, and the tanks which were supplied by Messrs. J. Oakes & Co. of Alfreton, Nottingham.

NOTICES OF MEETINGS.

VACCINATION OFFICERS' ASSOCIATION.

The next meeting of members of this association will be Saturday, September 20, at 2.30 P.M., at the Charing Cross Medical School, 6a Chandos Street, Strand, W.C.

AGENDA.—1. To read minutes of last meeting. 2. Correspondence. 3. The election of members and honorary members. 4. To discuss the half-yearly returns of vaccination as sent to the Local Government Board on August 7. Members are requested to bring same. 5. To discuss the resolution carried by the St. James' Hospital on July 16, 1884, as to the advisability of transferring public vaccination from boards of guardians to vestries, and to move a resolution in favour of the same.
C. O. ELKERTON, Hon. Sec.
30 Clarendon Street, Finsbury.

COMPETITIONS.

THE examination for certificates in Sanitary Science by the University of Cambridge will begin on Tuesday, October 7. The candidates, who must be on the *Medical Register* of the Kingdom, should be sent to Dr. Annington, Cambridge, on September 28.

APPOINTMENTS UNDER THE PUBLIC HEALTH ACT.

MEDICAL OFFICERS OF HEALTH.

ADKINS, George, L.R.C.P.Lond., M.R.C.S.Eng., L.S.A.Lond. has been re-appointed Medical Officer of Health for the P. St. Mary Rural Sanitary District, at £150 per annum.

BATES, Charles Pope, M.R.C.S.Eng., L.S.A.Lond. has been appointed Medical Officer of Health for the Ramsey Sanitary District, at £25 for one year.

BROCKLEHURST, Thomas Howard, M.R.C.S.Eng., L.S.A.Lond. has been appointed Medical Officer of Health for the Urban Sanitary District, at £12 for the year ending 1885.

DANIEL, Woodruffe, M.R.C.S.Eng., L.S.A.Lond. has been appointed Medical Officer of Health for the Wareham Sanitary District, at £10 for one year.

DEAN, Francis, M.R.C.S.Eng., L.S.A.Lond. has been appointed Medical Officer of Health for the Northleach Rural Sanitary District, at £100 per annum (in addition to £25 per annum as Medical Officer to the Union Workhouse), etc. resigned.

EVANS, William, L.R.C.P. Edin., M.R.C.S.Eng. has been appointed Medical Officer of Health for the Angleson Sanitary District, at £105 for one year.

FENTON, Mark Anthony, M.D. Univ. Dub., L.R.C.S. Irel. has been re-appointed Medical Officer of Health for the Coveon Sanitary District, at £250 per annum.

FREER, John Henry, L.R.C.P.Lond., M.R.C.S.Eng. has been appointed Medical Officer of Health for the Regent Sanitary District, at £10 per annum, for three years.

FUSSELL, Dr. Edward Francis has been re-appointed Medical Officer of Health for the Newhaven Port Sanitary District, at £100 per annum, until March 25 next.

HAINES, Alfred Henry, M.R.C.S.Eng., L.S.A.Lond. has been appointed Medical Officer of Health for the Long Sutton Sanitary District, at the rate of £10 per annum until 1885 next.

HORS, Henry, L.R.C.P. Edin., M.R.C.S.Eng. has been appointed Medical Officer of Health for the Southampton Port

District, at the rate of 50 guineas per annum, until March 25 next, *vice* Bencaft, deceased.

JACK, Charles, M.D., C.M. Univ. Glasg., has been appointed Medical Officer of Health for the Horsforth Urban Sanitary District, Yorkshire, at £15 for one year, *vice* Libbey, resigned.

JEFFERY, Edward, M.D. Univ. King's Coll. Aberd., M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Lowestoft Urban Sanitary District, at £90 for one year.

ONES, Richard, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Flint Urban Sanitary District, at £25 for one year.

75. Francis Daniel, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Wareham and Purbeck Rural Sanitary District, at the rate of £100 per annum, till June 24, 1885.

ARTHRIDGE, Samuel, M.R.C.S. Eng., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Darlaston Urban Sanitary District, at £40 per annum.

MYTH, William John, M.D. Q. Univ. Irel., L.R.C.P. Edin., L.R.C.S. Edin., has been re-appointed Medical Officer of Health for the Baildon Urban Sanitary District, at £20 for one year.

YSON, Edmund John, L.R.C.P. Edin., L.R.C.S. Edin., has been re-appointed Medical Officer of Health for the Caxton and Arrington, the St. Neot's, and the Whitlesey Rural Sanitary Districts, and the St. Neot's Urban Sanitary District, at £277 for one year.

HOMERSON, Abram, M.D. Univ. St. And., M.R.C.S. Eng., L.S.A. Lond., has been appointed Medical Officer of Health for the Grange Urban Sanitary District, Lancashire, at £15 per annum, *vice* Page, appointed an Inspector under the Local Government Board.

WALLIS, Frederick Michael, M.R.C.S. Eng., L.S.A. Lond., has been appointed Medical Officer of Health for the newly-formed Bexhill Urban Sanitary District, at £10 per annum.

SURVEYORS, CLERKS TO GUARDIANS, INSPECTORS OF NUISANCES, &c.

BILLINGHAM, Mr. Thomas, has been elected a Member of the Bromsgrove Local Board and Improvement Commissioners (the Urban Sanitary Authority), *vice* Hadley, resigned.

BROADBENT, Mr. James, Branch manager of the Manchester and Liverpool District Bank, has been appointed Treasurer to the Corporation and Urban Sanitary Authority of Congleton, *vice* Krinks, resigned.

BUDDEN, Mr. Harry, has been re-appointed Surveyor and Inspector of Nuisances to the Corporation and Urban Sanitary Authority of Basingstoke, at £160, for one year.

CANTRELL, Mr. Thomas, has been appointed Accountant to the Corporation and Urban Sanitary Authority of Batley, at £200 per annum, *vice* Binns, deceased.

COPLAND, Mr. G. A., has been appointed Surveyor, Inspector of Nuisances, and Collector to the Loftus Local Board and Urban Sanitary Authority, Yorkshire, at £135 per annum, *vice* Stainthorpe, appointed Surveyor and Inspector of Nuisances to the Eton Local Board and Urban Sanitary Authority.

CRAWFORD, Mr. Charles Walter Payne, has been elected Chairman of the newly formed East Grinstead Local Board and Urban Sanitary Authority.

CROSS, Mr. John, Manager of the Poole Branch of the National Provincial Bank of England, Limited, has been appointed Treasurer to the Town Council and Urban Sanitary Authority of Poole, *vice* Hornsby, resigned.

DALES, Mr. Robert, has been elected a Member of the Walsoken Local Board and Urban Sanitary Authority, *vice* Kerridge, resigned.

DAVIES, Mr. E. A., has been elected a Member of the Barking Town Local Board and Urban Sanitary Authority, *vice* Pitt, resigned.

DAVIS, Mr. Stephen Joshua, Manager of the Dartford Branch of the London and County Bank, has been appointed Treasurer to the Dartford Local Board and Urban Sanitary Authority, and to the Dartford Guardians and Rural Sanitary Authority, *vice* Smith, resigned.

DEVE, Mr. J., late Surveyor to the Oldbury Local Board and Urban Sanitary Authority, has been appointed Consulting Surveyor, at £75 per annum.

DODSON, Mr. Richard, has been appointed Collector of Market Tolls to the Corporation and Urban Sanitary Authority of Ripon, at about £30 per annum, *vice* Marshall.

BARLAND, Mr. William, has been re-appointed Inspector of Nuisances for the Barnstaple Urban Sanitary District, Devon, at £80 per annum, from June 24.

MOODARD, Mr. Daniel, has been re-appointed Surveyor and Inspector of Nuisances to the Corporation and Urban Sanitary Authority of Kendal, at £140 per annum.

MOODWIN, Mr. W. M., bank manager, has been re-appointed Treasurer to the Bakewell Local Board and Urban Sanitary Authority, until March 25 next.

ARMON, Mr. John, has been appointed Inspector of Nuisances for the Rhyll Urban Sanitary District, at £70 per annum, *vice* Freeman, resigned.

AD, Mr. George Serle, banker, has been appointed Treasurer to the newly formed East Grinstead Local Board and Urban Sanitary Authority.

BLAND, Mr. John, has been elected a Member of the Oldbury Local Board and Urban Sanitary Authority, *vice* Rae, resigned.

WENES, Mr. W., has been re-appointed Inspector of Nuisances for the Bilston Urban Sanitary District, at £90 per annum.

CROSS, Mr. Joseph, has been elected a Member of the Withington Local Board and Urban Sanitary Authority, *vice* Whitworth, retired.

JONES, Mr. Oswald Flint, has been appointed Accountant to the Corporation and Urban Sanitary Authority of Eastbourne, at £200 per annum.

KASSELL, Mr. Edward, has been appointed Clerk, Surveyor, Inspector of Nuisances, and Collector to the Kirkby Lonsdale Local Board and Urban Sanitary Authority, at £70 per annum, *vice* Kemp, resigned.

KERRIDGE, Mr. James, has been appointed Surveyor to the Walsoken Local Board and Urban Sanitary Authority, at £20 per annum.

LANE, Col. Henry, has been elected Chairman of the newly formed Bexhill Local Board and Urban Sanitary Authority.

LANGHAM, Mr. Frederick A., solicitor, has been appointed Clerk to the newly formed Bexhill Local Board and Urban Sanitary Authority, at £25 per annum.

MOUNTAIN, Mr. Arthur H., has been appointed Surveyor to the Swinton and Pendlebury Local Board and Urban Sanitary Authority, at £140 per annum, *vice* Hooley, appointed to the Irwell Rural Sanitary Authority.

PENLINGTON, Mr. Robert Napier, has been elected a Member of the Dodworth Local Board and Urban Sanitary Authority, *vice* Senior, resigned.

RANGER, Mr. George, has been appointed Collector to the newly formed East Grinstead Local Board and Urban Sanitary Authority.

RAYMENT, Mr. William James, has been re-appointed Inspector of Nuisances for the Lowestoft Urban Sanitary District, at £60 for one year.

SMITH, Mr. Sydney, has been appointed Surveyor and Inspector of nuisances to the newly formed Bexhill Local Board and Urban Sanitary Authority, at £50 and £50 per annum.

SMITH, Mr. William, has been re-appointed Inspector of Nuisances for the Bakewell Urban Sanitary District for the year ending Sept. 20, 1885, upon the same terms as before.

SNOWDEN, Mr. David, has been appointed Collector to the Corporation and Urban Sanitary Authority of Louth, at fourpence in the pound Commission, until March 25 next, *vice* Brotherton, deceased.

SPEIGHT, Mr. William Watts, has been appointed Inspector of Nuisances for the Doncaster Rural Sanitary District, at £160 for one year, *vice* Wright, deceased.

LOCAL INTELLIGENCE.

EAST GRINSTEAD LOCAL BOARD AND URBAN SANITARY AUTHORITY.—The first election of members has resulted in the return of Messrs. Edward Smeed by 304 votes, Henry Padwick 281, Charles Taylor 252, John Southey 230, John Tooth, 220, C. W. P. Crawford 216, William Vicars 200, George Bailey 154, Charles Abraham 130, Charles Henry Galtie 104, James Charlwood 90, and Abraham Foster 70. There were thirty-four nominations for the twelve seats.

LOWESTOFT IMPROVEMENT COMMISSIONERS AND URBAN SANITARY AUTHORITY.—At the annual election on September 4 the following (all retiring commissioners by rotation) were re-elected—viz. For the East Ward—William Hinchman Clibben, Alfred Wilkinson, Robert B. Capps. For the West Ward—Adam Adams, William Mobbs, John Sampson Cragg. For the South Ward—John Lenth Clements, Alfred Lawrence, Edward Kettison Harvey.

BILTON IMPROVEMENT COMMISSIONERS AND URBAN SANITARY AUTHORITY.—At the annual election on September 4 the following were elected for the ensuing three years—viz.: Messrs. George Orison, with 126 votes, James Bird, 118, Thomas Jervons, 63, Thomas Price, 42. (Retiring commissioners re-elected.)

BLINCOMB IMPROVEMENT COMMISSIONERS AND URBAN SANITARY AUTHORITY.—At the annual election on the 4th instant the following were elected Members of the Board for the ensuing three years—viz.: Messrs. F. A. Lake, 219 votes, W. Whitaker, Esq., S. Taylor, Esq., W. Fisher, Esq., W. Handley, Esq.

The Holywell Rural Sanitary Authority recently appointed Mr. A. Cardoc Williams Inspector of Nuisances, but the Local Government Board declined to confirm the appointment, stating that Mr. Williams, being a minor, could not, they were advised, hold it.

BETHNALL. Sesser, has been constituted a Local Government District, with a Board of nine members—viz. Messrs. Arthur Sawyer Brook, Joseph Brown, Henry Lane, Samuel Ockenden (Junior), Jesse Oliver, Samuel Scriven, W. J. Smith, Thomas O. Thwaites, John Weston.

Chesham has at length been constituted a Local Government District, with a Board of nine members. The nominations are to be made by the 18th instant, and the voting papers to be issued on October 4, and collected on the 9th. Mr. Daniel Clare has been appointed the returning officer.

The Town Council and Urban Sanitary Authority of Wells, Somersetshire, have increased the salary of Mr. Charles Brown, the Surveyor, from £50 to £55 per annum.

The Paignton Local Board and Urban Sanitary Authority have increased the salary of Mr. John Fane Stone, the Medical Officer of Health, from £50 to £55 per annum.

The Barnstable Town Council and Urban Sanitary Authority have increased the salary of the Inspector of Nuisances from £50 to £55 per annum.

The Parish of Menai Bridge or Llandysilio has been constituted a Local Government District with a Board of nine Members, and Mr. M. Bulkeley Pryce has been appointed Returning Officer.

The Tunbridge Wells Local Board and Urban Sanitary Authority have, upon the recommendation of a Committee, increased the salary of Dr. William Stamford, the Medical Officer of Health, from £100 to £120 per annum.

The Staines Local Board and Urban Sanitary Authority have increased the salary of Mr. J. G. Gubbins, the collector, to £50 per annum.

The Chertsey Rural Sanitary Authority have, with the sanction of the Local Government Board, increased the salary of the Inspector of Nuisances from £100 to £120 per annum.

The Mansfield Improvement Commissioners and Urban Sanitary Authority have, upon the recommendation of the Sanitary Committee, increased the salary of Mr. Edward Clayton, the Inspector of Nuisances, from £60 to £80 per annum.

The Flint Town Council and Urban Sanitary Authority have increased the salary of Mr. Hugh Owen, the Surveyor, to £50 per annum.

The Nottingham Urban Sanitary Authority are not, at present, taking any steps to appoint a successor to Dr. Santon as Medical Officer of Health. Although he has been appointed to St. Luke,

Chelsea, he will continue to perform the duties of the former office for some time.

The Castleford Local Board and Urban Sanitary Authority have increased the salary of Mr. Ebenezer W. Kemp, the Medical Officer of Health, from £50 to £55 per annum.

The Maldon Rural Sanitary Authority have voted £50 to Mr. Alfred B. Brady, their Surveyor, for extra services in connection with the sewerage works.

At a meeting of the Sanitary Committee of the Town Council and Urban Sanitary Authority of Stamford on the 15th ult., three letters from the Local Government Board were read, relating to the appointment of a Medical Officer of Health, and the proposed reduction of salary from £50 to £40 per annum. The committee stated that 'looking to the circumstances of the district and to the important nature of the duties devolving upon Medical Officers of Health, it appears to them that the salary hitherto assigned was an affording more than an adequate remuneration for the efficient discharge of those duties.' After a long discussion, the following resolution was passed unanimously:—'That in the opinion of the Committee a salary of £50 a year is an adequate remuneration for the efficient discharge of the ordinary duties devolving upon the Medical Officer of Health for the borough, and that the Town Clerk inform the Local Government Board of this resolution.'

The long contention between the Stamford Rural Sanitary Authority and the Local Government Board upon the proposed reduction by the former of the salary of the Medical Officer of Health from £50 to £40 per annum, came to an end at the meeting on the 16th ult., when a letter from the Local Government Board was received and read, saying that 'the period for which the Medical Officer of Health was appointed, expired on March 25, and that it was obligatory on the Rural Sanitary Authority to appoint such an officer. The Board, therefore, trusted that the Authority would, without delay give its whole subject their careful consideration, and submit a satisfactory proposal for the future discharge of the duties of the office. The matter was then deferred to the next meeting on the 29th ult. After considerable discussion, it was decided, as a compromise, to re-appoint Dr. Reid at £50 for the present year. As Mr. Dancer, the Inspector, promised to use his influence with the Board above to agree to it, they will doubtless do so, and thus end a very disagreeable business.

The Exmouth Local Board and Urban Sanitary Authority have, upon the recommendation of the Finance Committee, increased the salary of Mr. Arthur Kempe, the medical officer of health, from £50 to £55 per annum.

Margam, near Neuch, has been constituted a Local Government district, with a Board of nine members, viz. Messrs. Christopher Rice Mansel Talbot, M.P., Arthur Pendarves Vivian, M.P., Walter Savours Powell, Benjamin Daniel, David Roderick David, David Davies, Thomas David, Thomas Gray, and Edward Jones.

STOKESBRIDGE IMPROVEMENT COMMISSIONERS AND URBAN SANITARY AUTHORITY.—At the annual election on the 4th inst., the following were elected commissioners for the ensuing three years, viz. Messrs. Henry James, with 203 votes, J. D. Penney, 197, and C. H. Collis, 191.

NOTES AND QUERIES.

Having for some time back been in the receipt of Queries pertaining strictly to sanitary work, and which it would be easy to answer, without having to refer our correspondent to competent professional advisers, we have opened a column in which to register such Queries and Replies thereto as can fairly be expected from us. Our subscribers and readers are invited to make such use of this column as will benefit themselves and the community. Both Queries and Replies will, however, be subjected, if unnecessarily long, to a strict condensation.

129. SEIZURE OF UNBOUND FOOD.

Can a person be convicted under Section 116 of the Public Health Act, 1875, for selling an article of food therein specified, either in a public market or elsewhere, the article being unfit for the food of man, or must the article first be found on the spot by an officer authorized? A case now stands thus. A person purchases some fish in a public market which are found to be unfit for food, they are taken to a medical officer of health, and he certifies, under the provisions of the Act, that they are unwholesome and unfit for food of man, and they are ordered by the justice to be destroyed. Can the seller be proceeded against?

[To express for sale, or to have possession of with intent to sell, things unfit for food is a nuisance at common law. (Nelson v. Thompson, 1 Q.B.D. 18. A 5 L.J. M.C. 183.) But in the case above stated, Sections 116 and 117 of the Public Health Act would not apply. The wording of Section 116 evidently requires that the medical officer of health or inspector of nuisances should inspect and examine any suspected article of food at the place of sale, and the section speaks of such articles, "exposed for sale or destined to be sold in any place for the purpose of sale or of preparation for sale." In the officer's judgment, the suspected article is of food a nuisance, or unwholesome, or unfit for the food of man, in any sense and carry away the same himself or by an assistant, in order to obtain a justice's order for its being destroyed or so disposed of as to prevent it from being exposed for sale or used for the food of man. The answer to the question asked must therefore be that the seller cannot be fined under Section 117, and it seems even doubtful how far the justice was within his legal powers in directing the destruction of the fish in question.—E.D.]

ORIGINAL PAPERS.

INAUGURAL ADDRESS.*

READ TO THE SANITARY INSTITUTE
OF GREAT BRITAIN.

BY SIR ROBERT RAWLINSON, C.B.,

PRESIDENT OF THE CONGRESS.

The year 1879 the Corporation of Dublin has taken in hand and has carried out various sanitary measures in the regulation of room-tenements, scavenging, improved abattoirs, and in labourers' dwellings. The purification of the Liffey is, however, a work which remains to be accomplished. Sanitary science is as old as time—that is, we find references to laws and means for preserving health in the oldest books as in the third book of Moses, Leviticus, reasons for some of the ceremonial regulations even now be easily understood, such as the use of unclean meats and isolation of contagious diseases—leprosy for instance. Leprosy in man, in garments, in sites, and in houses; the means for the purification, by burning, of tainted garments, and the pulling down and burning of the materials of leprosy houses may, with slight modifications, be adopted by Christian communities in all times. There are at this day what may be called leprous sites, produced through ages of contamination by human excreta, upon which dwell leprous-tainted houses, and in which dwell leprous inhabitants, having about their persons rags as clothing. That something akin to leprosy exists in sites and in houses may be seen from the fact that in our great towns, certainly, hospital surgeons recognise types of disease, and these the most malignant and deadly, arising from special streets, and even from particular houses; and when, to accomplish certain sanitary measures, these houses, streets, and inhabitants are removed, that type of disease ceases. A terrible condition, under which causes of both infectious and contagious, undoubtedly have not been fully recognised, so as to be met against and prevented. We shall, I trust, find something practical from some of our members to show the necessity there is for a readier and fuller recognition of the outbreak of certain diseases which tend to spread with great rapidity when once begun.

On the other hand, one of the greatest works to be accomplished by sanitarians will be to stem the tide of sanitary ignorance now working so much mischief, and causing incalculable human misery, by any useful degree lessening the fearful sting.

It is not necessarily the duty of sanitarians to teach the doctrine that dirt and disease are in all cases cause and effect, neither is it their duty to teach that they are not. Dirt is to be removed or ; disease is, as much as possible, to be prevented so far as human agency extends men strive for a sound mind in a sound body.

Do not suppose that, however much sanitary science may aid in the promotion of comfort and reduction of disease, it will ever carry it to the verge even of full prevention, as there

are cosmical causes which are, and ever will be, beyond human control. Excesses of heat, excesses of draught, and excesses of cold have destroyed vegetable, animal, and human life over vast areas of the earth's surface almost to extinction, and there is nothing more certain than that cosmical changes in the seasons similar to those which have occurred in the past will be repeated in the future. We know nothing of the origin of life. We move at the bottom of an atmospheric ocean over which we have no absolute control; the composition of which, in bulk, we cannot alter. We find health under certain conditions; malarial disease and death under others, and how little can we effect these elements one way or the other? Let us note what are the elements we have to consider. The sun furnishes heat to evaporate the ocean water, and out of these elements proceed our meteorological changes. The vapour, invisible at first, forms into cloud, which again condenses into the form of snow, hail, dew, and rain, precipitating these over ocean and land. Clouds aggregate and brew up tornadoes and tempests, to settle down into the gentle and refreshing shower and breeze. All the pure water in springs, streams, rivers, and lakes, has been cloud-conveyed from the salt ocean to the sources and sites where we find it.

Modern sanitary science may dictate, as simple remedial measures for cities, main sewerage and house draining, with improved water-supply. But will such costly works, when executed and left alone, prevent cholera? We fear the reply must be, 'Certainly not;' they are its foundation: but without other costly works of street-forming, paving, channelling, and persistent continuous good scavenging, most of the expenditure may have been wasted, as disease will continue to haunt defective and overcrowded room-tenements and unventilated houses. In some large seaport towns the poor live below the ground water-level; but in cities like Glasgow, Edinburgh, and Dublin the poor live in attics and tenement-houses, so that sewerage, draining, and scavenging is of little avail unless something further is done in the way of excreta removal, water-supply, and cleansing. In Dublin there are main sewers and drains, with a full supply of water, for the better classes; but, at the time of my inquiry (1879), for the poor who lived in room-tenements, there was no useful drainage, and practically no useful supply of water. There was no privy accommodation for the occupant of a room in a Dublin tenement. There was no water but at an external stand-pipe, situate at a distance, and involving labour to fetch and carry. A medical officer, when asked how the sick poor managed in the long nights of winter, replied, 'They use any utensil handy;' and when further asked as to their supply of water in the day-time, the reply was, 'a use of the same vessel for the water.' But Dublin is not by any means exceptional, as the town houses, room-tenements, and country cottages all over Great Britain, as also over every portion of the world which is inhabited, are dens filthy and swarming with vermin, because overcrowded, uncleansed, and under-ventilated. Of a truth, this question of house accommodation for the poor is the question of questions both for philanthropists and for statesmen, as here are the breeding dens of the roughs of all countries, nations, and tongues; in the single rooms are the seed-beds of disease and revolutions.

The saying that 'cleanliness is next to godliness'

must not be taken as an axiom which cannot be disputed. That cleanliness has not been, and is not now, in many countries, considered necessary to godliness, religious ceremonials, both heathen and Christian, amply prove. Nations professing Christianity do not to this day practise cleanliness as ordained by Moses, and explained in Leviticus. But the Levitical laws—which inculcate cleanliness—indicate the existence of filth and filthy habits amongst the populations for whom they were devised. The Jews, as a nation, were not road-makers or bath-builders, as were the Greeks and Romans in their day of governing power; neither have we in Great Britain public baths which can rank with those which existed in Imperial Rome, though recently baths in private houses have become common, and public baths and washhouses have been and are being established by our principal municipal authorities.

It is now some thirty years since I first prepared a set of suggestions for the instruction of sanitary engineers, which have been accepted and applied in Great Britain and on the Continent, in British colonies, in British India, and throughout North America. As I have recently revised these suggestions, I propose to refer to them in this address, to give it practical value.

Houses should stand on a dry subsoil, and in all cases, for the cottage as for the palace, the area within the walls should be covered by a layer of concrete. Sites for houses should not be dug into the side of a hill, unless the subsoil is drained and the main walls are effectively isolated from the high ground behind. All house-walls should, at the foundation, or immediately above it, have a damp-proof course to prevent rotteness, which leads to the Levitically described leprosy. Sewers and drains should not be formed within the basements of houses. To every room in a house there should be means for fresh air ventilation. To every room to be occupied, day or night, there should be means for external daylight. Refuse should not be stored near any dwelling-house until it becomes putrid, but should be removed at short intervals.

There should be unceasing day by day scavenging. Villages, where the cottages are apart, cannot with advantage be sewered as houses in towns are; but they may be surface-drained, and have earth latrines, to be cleansed each week by a paid scavenger. The payment of one or more shillings per week to a selected resident labourer in proportion to the number of cottages.

A clean water-supply is necessary for country cottages. Springs of water may, in some cases, be brought from a distance cheaply by pipes to the centre of the village. The economy of such process may be thus illustrated: A gallon of water weighs 10 lbs. Five gallons of water weigh 50 lbs., and 365 times 50 lbs. for one year, and fifty cottages in a village, would require this weight, with the weight of the can or bucket added, to be carried from any spring. The total weight would be about 900 tons. This water, if piped, will flow to any convenient point and save to the villagers so much labour. This is a question for the consideration of Boards of Guardians and landlords. I have recently seen in North Wales, on the estate of H. D. Pochin, Esq., J.P., isolated farmhouses fully supplied with water brought half a mile by a pipe half-inch in diameter.

A water-supply to a town should be general. The source should be pure. The water should be filtered

and stored in covered reservoirs. The supply should not fall below fifteen gallons per head of the population; it should be at high pressure and service. Hand-carried supplies should not be rated. There should be full and ready access for fire service.

It is practicable to take a supply of water every yard, every house, and every room, and to supervise and manage these services to reduce waste and bring about economy. This, however, can only be done by unceasing supervision.

One difficulty to be contended with is the thoughtless improvidence of the poor, and instances of their mischievous disposition, dishonesty, as pipes of lead may be stolen. Iron tubes may, however, be used for house drains, as they are both cheaper and stronger than lead, and the metal, having no value, will not be stolen. And water under pressure, if mischievously used with in any tenement, will be so disagreeable to those who wilfully liberate it will soon close, or, if damaged, cry out for repairs, and again readily bring upon themselves the same and trouble. There are many towns in which where each cottage has an independent supply of pure water at their own taps, constantly maintained at a rent-charge of one shilling each quarter.

Where water is brought in there should be a drain and sinks to remove the waste-water. The pipes should not in any instance enter the house, but sewer direct, but deliver over a small gulch connected with a drain. New houses in towns are recommended to adopt this method, and houses in London do adopt it. Town sewage-utilization, and river and stream purification are complicated questions in which there have been many mistakes, and out of which has arisen much litigation.

The true purpose of town-sewering should be to remove all waste-water as generated; to dry subsoil, and so to dispose of sewage so as to cause no nuisance. Town-sewering is a science now in the course of maturing. I have already several volumes published on the subject in England, in America, and on the Continent.

Main-sewering, as now inculcated and practised, only dates from about the year 1845.

About 1852 I drew up fresh rules for main-sewering and house-draining, recommending that the cost should be proportioned to the special work which would be required to accomplish it.

Natural watercourses were not, as in the country, and in the City of London, to be formed into conduits. Surface-water was to be as far as practicable discharged by the ordinary watercourses at and over the surface. Neither sewers nor drains were to be laid within the basements of houses. House-drains were to range from four to six inches in diameter, and were in all cases to be of cast-iron or of ware-pipes. The main-sewers were to be laid in right lines and have true inclinations; at changes of line or gradient manholes were to be formed having side-entrances on the largest class of sewers, but movable covers on the small sewer manholes; these arrangements are to facilitate inspection and cleansing by the Sewers and drains to be fully ventilated.

Any town sewered and drained on these principles is to be at all times under the inspection of the Sanitary Authority. The sewers being true in line can, from manholes, be seen through. At the surface,

of sewer can be sighted from manhole to lamphole, so that the surveyor knows exactly where to sink to find a side-junction. In the modern sewers side-junctions are to form part of the first construction, so that house-drains may join without any charge of any sort for making such junction.

Under the old system of sewers no line was kept, but the trenches were opened out in short lengths, and the sewers were constructed irregularly, both in line and gradient. Side-junctions were not formed, neither are they formed now on some of the metropolitan parish sewers, which are not under the general law, but the sewer is broken into, and the builder pays a fine for making the junction which ought to have been ready for use as part of the original construction. One effect has been that hundreds of large West End houses in London have never had the sewer opened to make the house-junction; so that the result has been house basement flooding, typhoid fever, and premature death.

Sewer and drain flushing with water is necessary to preserve these conduits clean. The automatic flushing tank is, therefore, an absolute necessity to the cleansing of drains and sewers. These flushing tanks—the invention of Mr. Rogers Field, C.E., one of the leading members of this Association—have become an absolute necessity. They accumulate any water turned into them up to the capacity of the tank, which may be from 50 to 500, or even 5,000, gallons, when, without further intervention, the entire volume of water is liberated at a regulated speed to flush the sewers or drains connected. The tank after each discharge fills again, and repeats the flushing operation at regulated intervals. Service boxes (small tanks), for flushing water-closets and urinals, are constructed on similar principles.

Sanitary science has been, and is yet, progressive. It is being studied by engineers both in Europe and in North America. In design and execution there are improvements, and, in some instances, the opposite. The complications connected with town sewerage are, however, so many and so various that definite rules to fit all places cannot be formulated. The problem cannot always be in the form of a rule-of-three sum; that is, rainfall, area, and main sewer capacity.

A sanitary engineer should, of course, be a meteorologist and a geologist; but then, why not also a botanist, as sewage develops strange growths. The engineer will study meteorology to learn the laws of the seasons, times, and volume of rain falling, not, however, to learn how large the sewers must be to remove the greatest volume of water falling in the least time, but how this water has passed away heretofore from the surface to be sewered, and with what effects.

Engineers, having much practice, will deal with each area specially, and construct their works so as best and most cheaply to accomplish the desired purposes—namely, to receive and remove wastewater and human excreta to some outlet or outlets, where they may be made harmless. Some engineers have thought that the heaviest known rainfall of a district must be provided for, hence calculations have been made as to capacities of sewers to remove some exceptionally heavy volume of rain within the hour; but if this rule were worked to, main sewers in our climate—for such populations as Birmingham—would have to be as large as railway tunnels. And for cities in India, such as Calcutta, Bombay, or Madras, main sewers of the dimensions of railway

tunnels would not serve, because rain occasionally falls at a rate of one inch per hour for many hours in continuance. The rule may appear absurd to those who have not studied the subject—namely, the heavier the rainfall, the less the capacity of the main sewers should be, as, during the period that such heavy rains continue, the entire surface is swamped—sewers, drains, and streets being alike under water.

In countries subject to these heavy falls of rain, there may be long intervals of excessive heat and dry weather, when at such times large sewers could only have a small volume of highly-concentrated sewage flowing through and evaporating rapidly, leaving sewage-sludge to putrefy and give off deadly gases. Sewers and drains in tropical climates must therefore be confined, in cross-sectional dimensions, to moderate volumes not exceeding some 150 gallons per head of the population. House-drains in no case need exceed 4 inches in diameter; and for establishments containing 1,000 persons, a drain of 9 inches in diameter will be sufficient.

In England, some towns having populations up to 10,000 have outlet-sewers from 15 inches to 18 inches in diameter, and these sewers have, in some instances, been working during the last thirty years, and have neither choked nor burst. Surface-water is not admitted. For valley-lines down which in former times flowed surface-water—small brook courses—the sewers must be of capacity to carry off floodwaters, there must also be overflows to the river, or there must be pumping-power to lift and discharge such storm-water above flood-level. But in these cases these surface-water channels ought not to have received sewage. This should have been removed by intercepting-drains.

This is a most important law which ought never to be disregarded—namely, do not inclose natural watercourses for main-sewerage purposes, because the volume of surface-water flowing down a small brook will be dry, or nearly dry, for long periods; whilst in storms it may be an angry rushing torrent, so that during all dry periods, sewage if turned in would stagnate, evaporate, and leave all the slimy deposit to corrupt and become dangerous. That which is true for a tropical climate is in a lesser degree true under any other climate.

About the beginning of this century, when water-closets began to be used in better class houses in London, large coarsely-made brick drains ramified the basements of houses, and were connected with the flat-bottomed sewers. Sewage—that is, wastewater and excreta—was turned into the sewers, and, becoming putrid, foul gases were generated, which, pervading the houses, produced fevers to so serious an extent that house-drain connection with sewers direct was forbidden by Act of Parliament. Then came in the crowning evil, the cesspool. Houses having water-closets were ordered to sever the connection with the sewers, and cesspools were formed in yards and gardens, and beneath basements, to receive the contents of the water-closets; and to this day large foul brick drains and cesspools exist beneath large old houses in the metropolis and at mansions of noblemen and gentlemen throughout the country. How many premature deaths have been the result it is not possible to enumerate. This mal-arrangement was headed by Windsor Castle, where previous to 1849 there were within the basement fifty-one cesspools full and overflowing. At Gwydyr House—the first Board of Health in 1848—nine

cesspools were found within the basement, all full and overflowing. At Bowood, the country seat of Lord Lansdowne, the entire basement was ramified with sewers, along which men could walk upright, all of them containing sewage deposit. This was the condition of the seat of Earl Grey at Hawick; then there were leaking brick sewers and drains at Spencer House, St. James's, London; at Marlborough House; the house of the Marquis of Bristol, St. James's Square, and at Claremont. These palaces and houses have, however, been thoroughly and effectively drained, and are now in good condition. The great colleges at Oxford were in a similar foul condition, but Christ Church, Balliol, All Souls, Jesus, and Wadham have been fully drained at a cost of about 5,000*l.*; and some 800 of the lodging-houses have been improved, cesspools and foul drains removed, new water-closets and new drains put in, impure wells and pumps done away with, and water supplied from the public works at a cost of some 15,000*l.* The population of Oxford is about 40,000, and the rateable value some 200,000*l.* The city has been sewered and drained, and pumping engines, with a sewage farm, established at a cost of not less than 200,000*l.*, so that Oxford has expended within a few years on sanitary works not less than 273,000*l.* But Cambridge remains, with all its colleges, an undrained, river-polluted cesspool city. Up to about 1821, Paris was a city of open privy cesspits and street pollutions, when an Ordinance was passed compelling the construction of watertight and so termed hermetically sealed cesspools, which continue to this day—nuisance creators and disease breeders. Neither London nor any other English town has ever been cesspooled as Paris is—that is, by such large and costly underground structures, and as a consequence, the smaller English cesspools have been more easily got rid of; and, since 1848, they have been abolished by tens of thousands, so that London, at this day, stands sewered, drained, and freed from most of its cesspools, and is in this respect the most fully water-closeted and cleanest great city in the world. The work of entirely freeing the river Thames of sewage from Teddington to the North Sea, is merely a question of time, and there will be no further tampering with the question in London; and out to sea also must go the whole of the crude sewage of Dublin, because the river Liffey must be purified, and intercepting-sewers, having a sea outlet, will be the cheapest remedy. Every large town in Great Britain which is situated on the seashore, or on the margin of a salt-water estuary, sends the crude sewage direct to the estuaries or to the sea, and I know no valid reason against it. There are undoubtedly manurial elements of value in crude sewage, but if it must cost thirty or more shillings to utilise it by deposition with chemicals, or in land irrigation, to earn twenty shillings, I fail to see that to dispose of it into the sea at a less cost in rates is waste.

There are two modes by which inland sewage may be treated to prevent its becoming a nuisance—by disinfection and precipitation, and by broad irrigation. Now, according to the most recent experiments on a practical scale, continued over a series of years, it has been found to cost about 3,000*l.* per annum to disinfect and precipitate the sediment from two millions of gallons of sewage per day, and the material obtained by precipitation has no paying value.

To treat the sewage of the metropolis, 160 million gallons per day, by chemical precipitation would cost, at a similar rate, about 240,000*l.* per annum, and if carried on at the existing outlets on the Thames would create a great nuisance. 240,000*l.* at twenty-five years' purchase would equal a capital sum of six millions sterling, which had better be expended in taking the sewage to sea, rather than in further attempting to deal with it inland.

For broad irrigation for London sewage there should be some 40,000 acres of land available, which, at 100*l.* per acre, would cost four millions sterling, and might cost four more millions sterling to drain, form roads and irrigation conduits; but no such area of land could be purchased for so low a price, if preceding examples are to be a test. It has been found that when land for sewage irrigation purposes has been taken compulsorily, the price has, in some cases, mounted up to 150 years' purchase, and is never less than three or four times the ordinary selling or letting value for ordinary agricultural uses.

Inland towns and villages, as a rule, are obliged to secure land upon which to effect sewage purification. A long list of such towns and villages might be made out, the chief towns being Birmingham, Wolverhampton, Doncaster, Nottingham, Bedford, Leamington, Oxford, Reading, Warwick, and Croydon; to name all would be to incur this Address with a long list of mere names, which can be found in Parliamentary returns, and which is being added to. There are other towns, such as Manchester, Leeds, Wakefield, and Bradford, where sewage is partially removed by sewers and partly by movable pails, and is treated by chemicals to cause precipitation. Irrigation, or filtration through land, produces the purest effluent, and, where suitable land can be procured at a fairly agricultural price, at the least cost to the community.

On the Continent there is a sewage irrigation at Dantzic, which has been in use some years, and on a large scale it is being adopted in Berlin, where there are large areas of flat surfaces of land with sparsely occupied sandy-subsoils. To utilise sewage in the easiest and cheapest manner, the sewage should flow on to the surface without pumping. The subsoil should be porous, the climate should be dry, and have a large average of sunshine. From such land good management would produce a profit.

Public baths, washhouses, disinfecting apparatus, mortuaries, abattoirs, and a scavenging department are all necessary.

Public baths, washhouses, and disinfecting apparatus, should be as near the population for whose uses they are intended as may be practicable. They should be plain in appearance, inexpensive, and fitted up with efficient apparatus. If twenty thousand pounds has to be expended in any town, it will be wiser to construct ten separate establishments placed where they are most wanted, rather than to erect one or two imposing-looking buildings to which the poor will not go—one reason being that they are too distant. Examples of the utter breakdown of grand and costly baths and washhouses may be given. The people for whom they were intended would not use them, and so the money they cost was wasted.

Disinfecting chambers should be attached to each washhouse establishment, but isolated. That is, infected clothing should be received and washed apart. To stamp out contagious disease, burning

or disinfection of infected bedding and clothing should be prompt. It will be the cheapest process to disinfect, wash, cleanse, and restore the articles to the poor owners free of cost rather than retard the process by using compulsion and demanding payment; as, in this case, there will be secretiveness and opposition; in the other case, ready compliance and thankfulness.

Mortuaries and ambulance-conveyances are an absolute necessity in towns, and should be a part of every establishment.

Public abattoirs, situate in open spaces, well drained and ventilated, are necessary. Private slaughter-houses ought not to be permitted.

A fire establishment is necessary; and in towns having a population exceeding 100,000 there may be several stations having electric communication with the head establishment.

Scavengers' Department.—This, I consider, a prime necessity. All forms of scavenging should be under the absolute control of the municipality. There should be no private scavenging. To require householders at any time to scavenge their own premises is a remnant of barbarism, as when it is so left it never has been done, nor ever will be done. Scavenging should be done at short intervals, and every spadeful of refuse should be cleared from the streets daily, being taken to some depot. Such of the refuse as will burn should be burned, and other forms of refuse should be harmlessly disposed of outside the town or city. It will be a mistake to retain any refuse which is liable, by keeping, to become offensive, in the hope of selling it to make a supposed profit, as it is not the business of a scavenger to sell refuse, but to produce cleanness. In seaport towns, if refuse cannot otherwise be disposed of, it may be sent to be sunk at sea in hopper barges.

In looking over the advances made in sanitary science, it must never be forgotten that to undertake and perfect good works is one thing, but that to maintain them good is the main thing.

It must also be remembered that sewers, drains, and waterworks are only means to an end—they are only good so long as they are sound, clean, and cared for. Again, the most complete works of sewerage and water-supply may leave untouched the slums and room-tenements: and these places may remain nests of contagious disease, out of which stalk the grim forms of typhoid and cholera. There are towns in England where sewers and drains have been formed and a good water-supply established, but where scavenging and single room tenement-inspection and cleansing have been shamefully neglected. The first should be done, the latter not left undone.

In the world there is no value but in human life, and human life has the greatest value when healthy and moral. It is the aim of the members of this Congress to induce improvement, to show statesmen and the public generally that the only safety will be in assisting to remove causes which lead to sickness, incapacity, and premature death.

FILTERS FOR EGYPT.—The Atkins Filter and Engineering Company, Limited, have received an order from the War Office for 3,000 Pocket Filters, similar to those supplied for the Transvaal and other expeditions, to be delivered within a week, Lord Wolseley having telegraphed for them. The firm have also in hand an order for nearly one thousand six-gallon stoneware filters, which they are now delivering to the Woolwich Dockyard.

ON THE UTILISATION OF TOWN REFUSE.*

By LAWSON TAIT, F.R.C.S.,

Chairman of the Health Committee of the Birmingham Corporation.

FEW of the many questions which have engaged the efforts of sanitary authorities during the brief period in which real attention has been given to the care of the public health has caused so much anxiety as the disposal of town refuse. In a few favoured places the difficulties have not been pressing, but in a town such as Birmingham, the rapidity of whose growth has been almost unexampled, and situated as it is in the centre of England, with a river no larger than a brook, the difficulties and the dangers of the disposal of refuse have risen to an extent probably unknown in other large centres of population. Fortunately, in the growth of the town, land has been easily obtained, so that the population has been widely spread. Had the growth been as rapid, and the area as curtailed as in the older towns, Birmingham, instead of being one of the healthiest of the large towns in England, would probably have had its death-rate heavier than any. From its situation on the highest part of the Midland district it was obliged to adopt in its early history the system of surface household wells, and until recently these had an almost universal prevalence throughout the town; indeed, they exist now in very large numbers. In close association the midden privy was constructed, and in 1871 there were nearly 20,000 of these centres of disease existing in the borough, their aggregate area exceeding thirteen acres. As by far the greater part of the town is built upon hills of loose sand and gravel, it is perfectly needless for me to say that soakage from the privies into the wells was of constant occurrence, and is still far too frequent. Of these privies about 14,000 drained at that time into the sewers. There were about 7,000 water-closets, the contents of which, together with all the road-sweepings, manufacturers' refuse, and countless other impurities, were turned, and had been ever since the town existed, into the small river traversing its area. It is not at all surprising, therefore, that the inhabitants on the banks of the river below the town raised strong objections to its being regarded as the common sewer. Injunctions were obtained, and the municipal authorities were obliged to give an undertaking to the Court of Chancery to apply an efficient remedy. The discussion as to what this remedy should be occupied the most earnest attention of the Town Council for several years, and it eventuated in the most complete and radical change of municipal policy which, I venture to say, has ever occurred in any town. Up to 1871 the government of the town was conducted upon lines which it is no part of my business here to discuss or condemn but no one who knows the town at all but will be able to substantiate my statement that the new régime inaugurated by the distinguished statesman who at the present moment presides over the Board of Trade, has, as it were, reconstructed every aspect of our municipal life. The town has improved in every possible way; its death-rate has fallen nearly five in the thousand, and the average age at death has been

* Read at the Social Science Congress at Birmingham, on Sept. 10, 1884.

raised six years, and the whole of these beneficial changes are due to the inauguration of Mr. Chamberlain's sanitary policy.

In addition to the fouling of the river of which I have spoken, another and very great element of danger existed in the fact that the contents of the middens, either with or without drainage into the sewers, had to be dealt with, as well as a large amount of household rubbish, which, were left to dry on the surface of the ground around the dwelling-houses, became a fertile source of danger and death. The problems we had to solve, therefore, were only two:—How we could treat the fluid impurities which ran into the river, and how we could dispose of the solid household refuse. Up to the time I am speaking of, and, indeed, up to the year 1878, with certain qualifications which I need not enter into, the contents of the middens and the solid rubbish were disposed of partly by sale to farmers, and partly by disposal upon tips. In the early history of the town, when it covered a small area, these tips were constructed upon pieces of land which are now almost in the centre of the town, and it has been by no means an unusual thing to trace outbreaks of zymotic diseases to the accidental reopening of these accumulations of the filth of bygone generations.

During our earlier experience the sale to farmers of a mixture of ashes and excrement was a fairly profitable transaction, but they soon discovered that the material sold them possessed little real value, and whilst the amount we had to sell constantly increased, the price obtainable just as steadily diminished, as will be seen from the following table:

Date.	Boats (of 25 tons).	Average price.
1876	405	£4.864
1877	1,442	4.257
1878	1,209	3.74
1879	1,603	2.44
1880	1,791	2.246
1881	2,038	2.053
1882	2,309	2.123
1883	2,397	1.7

The difference in price from 1876 to 1883 of 2,397 boats is 7,990/. The farmers, in fact, found that whilst the ashes clogged the land, the amount of fertilising material was so small as to be hardly worth the labour of application. We, on the other hand, found that not only was the price to be obtained for it constantly diminishing, but that the difficulties and cost of its transport were constantly increasing. The outlying rural districts in the immediate neighbourhood of the town, which were governed previous to 1875 without any kind of reference to sanitary work, were constituted into sanitary areas, with boards of management, who speedily found that it was not to the interests of their constituents that accumulations of this material should be allowed to lie on the canal sides within their boundaries. The canal companies, too, began to raise difficulties about transit, and about the damaging nature of this particular kind of traffic alike to their trade and their property; and the immense importance to us of this difficulty may be, perhaps, best summarised when I say that in the last few months one of the canal companies has given us notice of an increased tariff, which would, on our transactions of the previous year, mean increased payments of between 4,000/. and 5,000/. per annum. Finally, let me say that the difficulty in the deterioration of the value of this crude manure

upon the amount we now produce represents a difference of income between 1876 and 1884 of more than 20,000/. a year.

The Health Committee, under whose direction all this work is carried on, has been more than once adversely criticised about an undue increase of their actual expenditure over that for which they have estimated, but it is perfectly clear that in the conduct of such a business as this nothing like even an approximately exact estimate can be formed, and whilst actually their greatest excess of expenditure over estimate was 3,342*l.* 17*s.* 10*d.* on a total expenditure of nearly 45,000*l.* a year in 1883, the committee have frequently been under their estimate, and the wonder is that a statement in any degree approaching accuracy can ever be made. The diminution of income on the old method of working is perhaps best seen by the following column of figures, which gives the total receipts from the sale of crude manure between 1877 and 1880, in which latter year a more scientific treatment of the town-refuse was introduced, and these figures indicate the very advantageous results during the last three and a half years obtained from the new method:—

Years.	£	s.	d.
1877.....	11,212	12	0
1878.....	11,556	1	11
1879.....	8,339	18	4
1880.....	7,879	1	10
1881.....	10,141	3	2
1882.....	11,622	3	3
1883.....	11,553	4	11
1884.....	14,000	0	0 (estimate)

From the figures I have given, which are, except the last sum, actual cash results, it will be perfectly evident that if the old system of mixing ashes and excrement for the purpose of sale had been continued and extended, nothing but bankruptcy could have resulted for the department.

The problems we had to solve were only two in number, and they were extremely simple in character; but they were extremely complicated, from the enormous bulk of the material to which they had to be applied, and it is from this chiefly that our progress in their solution was so slow. We found, in fact, that theoretical chemistry was of but little help, and that laboratory experiments were absolutely futile. We found that no results of a trustworthy character could be obtained unless the experiments were made upon a scale which would represent a considerable fraction of the material we had to deal with. We were therefore obliged to proceed slowly and with the utmost caution, and, looking back upon the fact that we could find absolutely no experience anywhere which we could apply to our own work, it becomes more and more astonishing to me that we made so few mistakes as we might have to place on record if an account of them were demanded. We sent out inquiries, and we visited by deputation all the large towns in Great Britain which were in any way comparable to our own, and these inquiries and investigations, concurrently with our experiments, occupied a period of nearly seven years. As they advanced, and as the results of our experiments became more accurate and more extended, the more certain did we become that the original conclusions established by the report of the Birmingham Sewage Inquiry Committee were those alone which were applicable to our town. The recommendations were as follows:—‘The exclusion of animal excreta from the sewers is, in the opinion

of the committee, essential both to the effectual treatment of sewage and to the health and comfort of the population, and they have arrived at the conclusion that this object may be attained by a reform of the system of exposed privies and open middens now prevailing in the town, and which defile the air, poison the water, and, by means of connecting drains, pollute the sewage.

The first principle we established, and we arrived at it chiefly from the disastrous experience of other towns, where it had not been adopted, was that it was absolutely essential to keep the two elements with which we had to deal—the household refuse and the excreta—entirely separate, and for this purpose we established a system of dual and joint collection which has proved perfectly satisfactory. In the reconstruction of closet accommodation we filled up the old middens and replaced them by simple closets, under the seats of which we placed large galvanised pans. These pans are coated inside from time to time with boiling tar, an operation which very much diminishes the smell and enables them to be easily cleaned. Somewhere near the closets are placed ash-tubs, either of wood or iron, into which the tenants are requested to place their household refuse, and they are strictly forbidden to empty slops into the pans. It took a long time to educate the population to the fulfilment of even these simple directions, and much trouble was encountered for several years in establishing the fresh arrangement. We found that many people objected to it, and clung with a mistaken but most affectionate pertinacity to the foul middens to which they had been accustomed. The arrangements for the collection of the pans and ashes were at first defective, and a good deal of outcry was raised from time to time against the objectionable smells which they emitted as they passed through the streets; but as the details became perfected one after another these objections ceased, and we were not troubled with any complaints. Indeed, the complaints now are all against the old system, for when the remaining middens have to be emptied the overwhelming stench which prevails all over the neighbourhood for some hours after the process is a never-failing theme of complaint for exactly the same people who, when they were accustomed to its nightly recurrence, thought it hardly worth mention.

The collecting vans are arranged to carry eighteen pans and about one ton of ashes, and the collection is made from each house on the average once a week. When the pan is removed it is covered by a lid, made to fit perfectly tight by means of a strong spring and a band of India-rubber, so that any smell is avoided. The ash-tubs are emptied into a special receptacle at the hinder part of the van. These vans are taken to our central dépôt, and there are subjected to processes of which I shall shortly speak.

Two objections have been and may be urged against the process, so far as I have described it. The first is of an unimportant character, the second of very great weight. The first is that as the work has to be done during the night some amount of noise is made at the back of each house once a week, but I venture to say, and I can speak from my own experience without any hesitation, that this is a very much smaller evil than the noise of emptying one of the old middens, which sometimes went on for hours, even though this occurred only once in several months. The outrageous stench which accompanied

this process was sufficient to induce one to be away from home when it occurred. The second objection is the cost of the collection, which is very heavy. The answer to it, however, is that the material has to be collected, whether it is deposited in tubs or middens, and when it is collected from middens it has to be removed out into the country at an additional cost, which more than doubles the cost of collection. If, on the other hand, it is collected in pans and tubs on the separate system, not only does the cost of collection practically end the loss which is sustained on it, but its further treatment on the plan I have to speak of contributes (as I hope to show) to a very remarkable extent to a set-off upon the cost of collection. Upon these grounds, therefore, in estimating the financial results of our proceeding we do not take in the cost of collection at all, because it occurs equally in both accounts, and therefore as a common factor may be entirely eliminated. We proceed, then, to discuss the whole question at the point where the material, of whatever type, has been received at the places we call wharves. There are several of these throughout the town, in all but one of which the old process is carried on; and it is to this one exception that the interest of what I have to say applies.

Whilst our system of collection and the details of reconstruction were being applied to the town, the amount of material collected at Montague Street far outstripped our powers of dealing with it by a scientific process. It had, therefore, to be converted by a primitive process of manufacture into what was practically the old midden stuff; and the only advantage we obtained so far by our new arrangement was that we had one huge midden in Montague Street in place of the thousands we had removed from the general area of the town. It was not difficult to imagine that this arrangement was extremely unsatisfactory to the inhabitants of the immediate neighbourhood of Montague Street wharf, and it increased the cost of the department very materially without any tangible gain beyond the increase of the health of the community. This increase of cost, together with the increase of population during the years in which the pan system was being extended, and the materials roughly manufactured was displayed in the following column of figures:—

Years.	Expenditure.	Population.	Cost per Head.
	£ s. d.		s. d.
1877	33,356 15 5	377,436	1 9
1878	35,101 3 0	383,117	1 10
1879	40,446 14 1	388,884	2 0

It will be seen that the continually increasing cost of collection and the continuously diminishing value of the material again gave indications that the continuation of that policy would have been ruinous. At this point it may probably be convenient to anticipate a criticism which is sure to be raised upon the general system of our policy for the disposal of refuse which has been adopted in Birmingham. Towns will be pointed to, of great importance and large size, in which no such costs as these are incurred, and instances of towns where the water-carriage system is in use will doubtless be specially indicated. We may, and probably will, be asked the question, Why has not the water-carriage system been adopted in Birmingham? and there are some amongst us still, I am sorry to say, who are disposed to take such a retrograde step. I need not answer the objection in detail, because the

answer to it will be found in the volume I have already quoted, the report of the Birmingham Sewage Inquiry Committee. Suffice it to say generally that as Birmingham has a very elevated position we cannot obtain a water supply by gravitation. Every ounce of water used in the town, unless obtained from a soft water cistern placed on the roof of a house, has to be pumped, and the public supply has to be raised from 200 to 600 feet, and I need not say that not only is this an extremely costly process, but that the quantity we can obtain, and from reservoirs, is such as is calculated only for the maximum requirements of a constantly growing population for all purposes exclusive of a water-carriage system of sewage. It is extremely doubtful if we could obtain in any way the additional quantity of water required for this purpose, and even if we could obtain it our difficulties would be increased instead of diminished by every gallon of water-closet liquid which was added to our already enormous bulk of sewage. It is stated in the report already quoted that in 1871 the dry weather flow of sewage was seventeen millions of gallons, and that the stormy outflow amounted to thirty-two millions of gallons each day, and from the very considerable increase of population, and the far more extensive processes now in existence, the probability is that these figures would now stand respectively at twenty millions and forty millions of gallons, all of which has to pass into a small brook. It is perfectly true that very large tracts of land have been purchased, and have been drained for the purpose of clarifying this enormous bulk of polluted water, but it is equally true, on the other side, that in the constitution of the Birmingham and District United Drainage Area an enormous additional area, with a very large population, has been embraced within its operations, the drainage of which will have to be passed over this land.

Looking at the condition of the river at the present moment, it is not difficult to believe that so far as the operations of the Drainage Board have proceeded the question of the clarification of the river has hardly been touched, and I may say that all the land they have will be absolutely ineffectual for dealing with the sewage during at least nine months in the year. Besides, there are three additional arguments which can be urged against any departure from the policy commenced in 1871 and consistently maintained until the present moment. The first is that when excrementitious matter is added to water it is absolutely impossible effectually to remove it by any process short of distillation. It is equally certain, as proved by the Sewage Inquiry Committee's report, that huge bulks of diluted sewage cannot be applied with any kind of economy to land, however extensive in area, and that the crops grown upon that land, such as rye grasses and the coarser kinds of vegetables, cannot be sold. The third objection is that human excreta contains so much valuable fertilising material that they constitute in themselves a perfect manure of great value for certain purposes. We can say further, from an experience which is now pretty extensive, that when they are reduced to a form in which they can be stored or transmitted to a distance, or applied directly to the land without further manufacture, they command a ready and profitable sale. The conclusion is, therefore, that the true economy is to preserve from waste these materials which, having

been taken from the land, should be restored to it, and that it is a mistake to waste them by such dilution as renders them practically valueless. In fact, in such an uncertain and moist climate as we have to contend with, the true principle for the utilisation of this kind of refuse is to remove from it all excess of moisture which it already contains, and certainly not to diminish its value by adding to it a useless and damaging excess of water.

Acting upon these principles, the plan we adopted was to act upon the one kind of refuse by means of the other. Immensely to our surprise, and to our no small satisfaction, we found that the solid ash-tub refuse, which amounts to 72,000 tons per annum, would burn in properly constructed furnaces without the addition of any other kind of fuel, and in this burning it is reduced to one-fourth of its original bulk, and the result is a peculiarly useful silicious clinker, which we turn to all kinds of useful purposes. It has been used to erect buildings with, to make roads and paving blocks, staircases, horse-troughs, tables, and ornamental fireplaces, samples of all of which may be seen at our works. Of this kind of household rubbish there has been about eleven boats per week sent out into the country, the mere cost of transit being 500*l*. If we burn the same amount the cost would be 270*l*., and if we used all the clinkers, as we hope to do, we should save 230*l*. The burning of this amount would occupy three furnaces of the kind we have erected for the purpose, and of the total bulk of the rubbish thus burned 75 per cent. would be dissipated in the form of heat. From the figures I have just given it would clearly be profitable if we merely burnt the rubbish, and did not in any way utilise the heat; but there is no physicist, certainly no manufacturer, who is not perfectly aware that one of the greatest advances of modern times has been in the utilisation of the waste energy which has a constant tendency to be dissipated in the form of heat. The loss would therefore be enormous if we allowed 75 per cent. of the energy contained in the 72,000 tons of this rubbish to be annually wasted.

In order to utilise this waste heat the plan adopted by the Health Committee was to apply it for the removal of moisture from the contents of the pails. The means by which this is done is extremely simple. Boilers are placed in the furnaces, and the heat is transferred by means of steam to large machines, of which a working model is here exhibited, into which about sixteen tons of pail stuff is put as a charge with sufficient sulphuric acid to fix the ammonia. A hot-air blast from the furnace flue is drawn through the machines by means of a blower. The steam is applied by means of a steam-jacket and hollow rotating spindles, and in from sixteen to twenty hours the sixteen tons is reduced to one ton of solid poudrette, containing from 7 to 9 per cent. of ammonia, according to the time of the year, and from 2 to 3 per cent. of phosphates. Without any further treatment or addition this forms an admirable manure for top dressings, and for all kinds of rapidly-growing roots, particularly the beet-root, and in the growth of those vegetables for the purpose of sugar manufacture this kind of manure has been found extremely valuable, and doubtless it will also have a ready sale for sugar-cane and cotton.

Concerning its commercial value no absolutely certain statements can be made. So long as we were making ten or fifteen tons per week, and until we

sified we could make a much larger amount, or very energetically enter into the question if we could obtain for it. We were quite to hand it over to a large firm of artificial manufacturers, who took all we made at 5*l.* without any reduction for carriage. When it rose to twenty and twenty-five tons per firm found the quantity larger than they could deal with, and we accepted a temporary reduction of price to 4*l.* a ton. During the last two years, however, we have been making efforts to get a better price, and we have had difficulty in getting 5*l.* a ton—in fact, we were unable to get as much as 7*l.* 10*s.* We also find the Corporation of Warrington can command a steady price of 6*l.* 10*s.* per ton for exactly the same material.

Our estimates of profit and loss in dealing with refuse, we found it convenient to take one ton of stuff as received at the wharf as the unit of sale. On the old system we found we lost every ton we collected. In the winter of 1882, when our machinery was very inefficient, only on an experimental scale, we were able to reduce our loss to 3*s.* 9*d.* per ton. In 1883 we collected nearly 18,500,000 of pails containing tons of stuff, and we estimate that if all this were manufactured into poudrette, and sold on the actual loss of 10,400*l.* a year would be turned into an actual profit of 17,000*l.*, giving a clearance of 22,000*l.* a year. As a matter of fact, when we sell the poudrette at 4*l.* a ton, we make a profit, or, to speak more accurately, we reduce our loss on every ton of pail stuff collected to 9*s.* 2*d.* If we obtained a constant price of 5*l.* a ton, the diminution of loss would be 10*s.* and if we obtained the Warrington price, the reduction would be 12*s.* 6*d.* a ton, and there is no doubt that these sums would immensely increase with an increased output, because we are fully conscious of the experience of all manufacturers, that there is a constant tendency towards an increase in the cost of production just as the production increases in amount.

In conclusion, let me say that whilst I am permitted to state the financial gain to the borough of Manchester from 14,000*l.* to 17,000*l.* a year, according to the price obtained for the manure, there is no doubt that these estimates are to a considerable extent speculative, but there is no speculation in the fact that we should save for the community a large quantity of valuable material which is now absolutely wasted; and there is considerable consolation in the fact that, whilst, as I have said in the course of this paper, our estimates never can be anything like exactness, yet we have been fully justified by results in placing our estimates of receipts on the sale of manure largely in excess of those of last year. In 1883 our total receipts were 11,553*l.* on the sale of manure, against 10,880*l.* in 1880, that is, before we began to sell poudrette. For this year we estimate our income from this source at 14,000*l.* On July 31 we had 7,069*l.*, and had 400*l.* due for stock in hand at delivery. As the best part of the year for poudrette has yet to come, and as we are quite confident that we can obtain an increase in price, we feel that on Dec. 31 our estimates of income from this source will be completely justified.

EDUCATION BY PROVERB IN SANITARY WORK.*

By ALFRED CARPENTER, M.D., M.R.C.P.Lond.,
C.S.S.Camb.,

Chairman of the Council of the Sanitary Institute of Great Britain.

THERE are two points in the study of the causes which shorten human life, which must strike all thinkers upon the subjects of health, of disease, and of death. These points may well form the commencement of my address to the earnest sanitarians who are now assembled in this city of Dublin.

The first of these points is the sacred feeling which attaches to human life, to the spiritual essence by which we live and move, and have active existence, and which feeling is instinctive in the breasts of all who may be assumed to have had the privilege of a spiritual contact with the Supreme Being. This spiritual essence being a something altogether different to that life which belongs to animated nature, exclusive of that attached to humanity.

The second is the carelessness with regard to this same life, the indifference with which its extinction is regarded by barbarians and uncivilised communities, and also by a portion of the civilised world, who ignore the existence of a Supreme and Benevolent Architect of the Universe. The more uncivilised the race, the less is the respect which is paid to the maintenance of human life. There are still nations upon the face of the globe who, when their parents or relations become old, or labour under any distemper which cannot be cured, cut short their days with a violent hand, in order to be relieved from the burden of supporting and tending them: and there are yet some countries in which the children are destroyed when not wanted, much as we destroy whelps and kittens in our own land. I have even in my own day, in our own native country, heard it represented that it would be an advantage to the State, to the locality in which they live, and even to the poor creatures themselves, if some of the inhabitants of our lunatic asylums, our prisons, and our workhouses, could be put to death in some painless way, by which their sufferings could be shortened here, and the expense which their maintenance entailed upon the community altogether avoided. There are also men who boast themselves as being among the highest of intellectual beings who would deal in a similar manner with the habitual drunkard, by placing within his reach as much as he wished to take of the baneful poison which destroyed his health, with the object of hastening his departure from among us, and so saving the State or his personal friends any further trouble and expense on his account. These individuals are but evidence of the brotherhood which exists between some of the tribes inhabiting the Chinese Empire, or of the interior of America with these same intellectual beings among Queen Victoria's subjects, who, like the barbarians referred to, ignore the sacred character of the vital spark, and have no idea of a future state. In this part of the world they call themselves philosophers, and style the subject a study of the Euthanasia.† But the sacred character which attaches to human life is not likely to be extinguished among us, and whilst the instinctive

* Lecture delivered at the Congress of the Sanitary Institute of Great Britain, at Dublin, on 1 Oct. 1884.

† Meaning an easy departure and utter annihilation.

feeling which belongs to humanity, arising from spiritual contact with a higher power, has sway, we are not likely to degenerate to a class of low utilitarians, or become the supporters of a principle of a cynical selfishness. A nation or a class encouraging a feeling which diminishes the sacred character attached to human life is a degenerate nation or an uncivilised race. This cannot be said of either the Celt or Saxon as a race, though some among us give utterance to doubtful principles. If there is one thing more than another which is uppermost in men's minds in this our day, and in our own land, it is as to how disease may be impeded, how our children may be preserved to us, and how we may attain to a length of days which statistics have told us should be ours, but is not. It is only within this present century that Society has been made aware of the loss which accrues to the community from the premature deaths of immense numbers of its atoms: personal interest is brought forward in support of humanity, and the welfare of the State is shown to be also in accord with the sacred feeling which protects the life of its citizens. Although the people generally had not been aware of this loss until very recently, it was well known to wise men in all ages, and imputed by them from various motives, either to the anger of the Supreme Being, or of those who in the more degenerate ages of the world represented Him in the public mind. The tenth plague in Egypt, in which the death of a child in every family was the natural result of a disobedience to sanitary law, ultimately led to the promulgation of the first set of sanitary edicts with which we are intimately acquainted, and which were made binding upon the Israelitish people by being engrafted upon their religious performances. It is thus that the wise men of old were enabled to 'save some' by means of Proverb or religious dogma, and the sanitary observances inculcated by Moses in the wilderness of Sinai were based upon his acquaintance with the evils of town life, and the disadvantages to the State which a residence in the closely confined cities of Egypt had brought upon the Hebrews. The forty years' wanderings in the air of the desert purified them from the diseases which had debilitated their frames, and which the fleshpots of the valley of the Nile had assisted to cause. The rules laid down by Moses, whilst they prohibited a continuance of the people in a nomadic life, also prevented those evils from arising which were sure otherwise to follow upon overcrowding and its natural consequences in the confined cities of Palestine. Moses was well acquainted with the selfishness and with the egotistical and mercenary spirit especially belonging to one side of humanity. He took measures, therefore, to inculcate sanitary truths by making them into edicts of the State, unalterable by the whims of the people, and this led them to be observed as long as the Mosaic law was the law of the land. Moses and other wise men of old studied human nature; they recognised the difficulties which were in the way of establishing healthy action, and pointed out to their disciples that health followed upon obedience to certain laws. They knew that self-indulgence, sloth, and the love of money, were stronger moving powers in the minds of the masses than benevolence, than industry, and virtuous abnegation of self. The spirit which led Moses to lay down the laws in the Mosaic precepts, which are the basis of all sanitary codification, led to the popular association of Proverb in sanitary work.

The same moving spirit caused the priests and priestesses of the temples of the gods of the heathens to give utterance to sound sanitary directions, veiled in dark sentences, and accompanied with rites and ceremonies tending to exercise the imagination, and to lead their devotees to carry out their behests in blind obedience, and without thought as to the reasons for their orders, or any reference to the God of Nature in the work to be done. But being myself an earnest believer in natural law, I understand Nature as being in the words of one of our poets, not only in the material and visible world—

In the round ocean, and the living air,
And the blue sky (*but also*) in the minds of man,

and that all actions which take place in the world, all changes of matter, and all the results of such, are caused by laws implanted by the Divine Architect of the Universe, in imponderable as well as in material agencies. I believe that the former, though invisible and unweighable, are infinitely more powerful than the latter; that the material world and its inanimate matter is acted upon by the immaterial and the spiritual world, through animated nature, in various ways, which may be beyond our conception, but which nevertheless are according to general laws, and that it is always in accordance with a law when disease of any kind appears, and life is taken away.

It is the object of the sanitarian to find out the forces, as well as the material agencies, which bring these laws into play, especially as regards those forces which influence the health of the people, by means of which life is prolonged or shortened, and the atoms which go to make up a population increase in number or diminish and vanish away. We ask, and we are sometimes able to find out in answer to our question, why those enormous animals which formerly inhabited the earth; why the megatherium, dinotherium, the mastodon, and the Irish elk have departed from amongst us; and coming nearer to present times, we ask why the Aztecs are gone, and the Red Indians are likewise becoming extinct, following in the wake of the elk and the moa, whilst the Celt and the Saxon are spreading all over the world, and showing their superior mental and actively constituted bodily powers in every portion of the earth, and spreading abroad a knowledge of the sacredness which attaches to human life. A belief in natural law, as far as the people generally is concerned, is a belief of modern growth, it is one of the pillars of sanitary work, the other has sprung out of the Christian tenet that we should love our neighbour as ourselves. The term supernatural is still considered as a reality by many, but it is obsolete and altogether out of date to the sanitarian in all things connected with health. If anything arises which is new, or rather which is observed now for the first time, or which is incomprehensible to him, the sanitarian believes it to be the result of some law, the nature of which is at present hidden from his intellectual understanding. If it has reference to the health and well-being of the people, he sets himself to solve the mystery, and to find out the bearings of that law which has brought about the apparently incomprehensible result; and whilst acknowledging that all things which happen are the sequences of Nature's laws, the sanitarian declines to regard anything as supernatural or beyond the power of man, to influence, sooner or later, for either

good or evil, if means are taken to effect the object he has in view.

For instance, an advanced sanitarian declines to look upon disease, or even upon death, as supernatural, and some of us dare to assert that death, when caused by disease, is not a necessary sequence in man's history. I, as a sanitarian, dare to assert that death, as it ordinarily occurs, is a preventable event, and that disease need not be the cause of death; and in effect I support the views held by those who uphold a belief in revealed religion, that disease is the sequence of man's degradation and fall, and that a restoration to right paths will be followed by the removal of its effects, and with its removal the sacred character which attaches to human life will be made still more manifest.

The sanitarian's study is man's mental as well as physical state; he is able to make out the effects which are produced upon his material body by immaterial as well as material agencies. Both have influenced his actions and his affairs from his first appearance on the earth. He finds that the acts of man are governed by natural laws; that they are often the sequences of acts which were performed by generations who existed in ages long past, and which acts are not ordinarily thought of as having been the causes of those results, and no country in the world gives such proof of the truth of this adage as this Ireland, in which population is decreasing and public health at a comparatively low ebb, whilst the sacred character which belongs to human life is not set at so high a rate by some of its inhabitants as it is on the other side of the Channel.

The sanitarian judges by analogy, and knows that the men of the present day will influence their successors hereafter in a similar manner, if corresponding acts are performed by ourselves. He can prove this fact by irresistible evidence, based, it is true, upon analogy, but the sequence of events, like the rising of the sun to-morrow morning, is all but certain. He appeals to you to assist him in taking such measures as shall prevent similar results in the future, when they may possibly produce corresponding evils to man. There is no proverb so well established as that of 'Prevention is better than cure,' or, as the old Roman expressed it, 'Præcipiis obsta;' and to it I appeal as one of the bases of my remarks.

The sanitarian shows you that whilst a few years ago the average age at death of all persons who died in a given period of time in some of our towns was not more than twenty-five years, and that some districts in Dublin at this moment show a similar rate in the length of life of those living in those districts, whilst in others it is thirty-five or forty; and that which is called, in irony, Civilisation or Culture, is partly responsible for the gradual decrease in the length of days of man's life upon earth; for the shortest average lives were in the most crowded, but also the most highly civilised cities. We are able to show you now that the average age of man at death has risen within the last few years to over forty-one (the whole kingdom being considered), whilst in some given districts it rises to sixty; and we assert that this increase in the length of life is due to sanitary work: to a better knowledge of the causes of disease among the people, and the removal of those incidences which belong to a neglected poverty.

We ask, Why should conditions exist in some of the bye-streets of Dublin, of London, and of Liverpool, or Glasgow, by means of which the average

age of those who die there is considerably less than thirty, whilst the instances in which life has been prolonged to 100 are numerous even in Ireland itself? The sanitarian asks, If Biddy Sullivan could live till after her ninety-ninth birthday, why should not the same result happen to every other person born in Ireland? Every sound seed produced by a given plant can be cultivated and made to produce another of the same kind if proper measures are taken to bring about the object in view; it is only a barbarian plan which leads to a so-called survival of the fittest. The sanitarian asserts that Bridge: Sullivan did not die, in the ordinary sense of the term, from disease. There was no apparent disease in her frame; there was evidence of age, which showed itself in the white hairs, the dim sight, the hardness of hearing, and the want of taste, which came on in the last few months of her life, like changes of colour which take place as a cornfield approaches the time of harvest; but those conditions arose from failure to carry out certain attributes which belonged to the material body. They were not attended by pain, and when life ceased to be, Biddy Sullivan shuffled off the mortal coil, and joined the majority without suffering a pang of any kind. I have in my time watched many and many a death-bed, and in the fact of death itself, as separated from the disease which has brought on the premature ending to mortal life, I am satisfied that pain is not and need not be a part of the process. There is no more pain in dying than in being born into the world; uneasiness connected with spinal actions there may be, but pain is no part of the process. 'I am in no pain,' has been the answer to my question hours before the end has come: the departure has taken place, the separation of soul from body has been effected without a pang of any kind. Pain is a consequence of disease. The end of mortal life on earth will come, but disease need not be its precursor, and death therefore need not be regarded as painful if disease is prevented. Bodily pain is the evidence of some abnormal action which is interfering with the ordinary course of nature; it is a danger-signal exhibited by the nervous system to show to the owner that some law has been transgressed, and some change effected in the nerve battery which regulates organic life, which has led to changes not consistent with health and freedom from suffering. Pain is the manifestation of a warning on the part of organic life which should cause the sufferer to alter some course of proceeding tending to set up mischief, or it is the necessary sequence of things in a return to a right and healthy path.

It is the object of the sanitarian to bring about conditions which diminish the frequency of early death, which assist to remove bodily pain from the list of human grievances, and to pave the way for that time when every person born into the world will enjoy his birthright without having it curtailed by the acts of other people. Every child born into the world has a right to live to the natural end of his mortal life, and, whatever is taken away from that one hundred years which is his birthright, is so much fraud upon him; and is so much enjoyment upon earth of which he has been robbed. The development which should be the result of that enjoyment has been prevented, and his hopes of a future and a brighter world possibly taken away, or if his sojourn is attended with suffering here, the pain endured is so much of the fire of affliction which helps to purify

the spiritual being and prepare it for that brighter world beyond the grave. A just and benevolent Maker will no doubt rectify this in some way beyond our ken, but the fact is there. That length of life which was attainable by Biddy Sullivan—viz., close upon a century, is the birthright of all of us. We do not attain to it because our forefathers did that which was right in their own eyes, without reference to the effect of their actions upon their descendants, as well as upon those around them: or our neighbours, or we ourselves, do acts inconsistent with its continuance. Our forefathers were ignorant of the influence their conduct would have upon their descendants. The sin of omission will not be so great to them as it will be to us, who have the illumination of the present age to guide us.

'*Salus Populi suprema lex*,' is a very old proverb in the cause of sanitation. It was a Roman saying when the commonwealth was the first thought of the true statesmen of that old republic, when a few great men cared for their country more than for their own pockets, and preferred its welfare to that of their own comfort; but the teachings of the proverb have had until quite recently but little force in the larger part of the United Kingdom, and certainly less in Ireland than across the Channel. That proverb in later times, however, has been more often used for purposes of persecution than for the public benefit, and any good effects which it might have had have been much more than counteracted by others which have shortened life and propagated disease, but which, curiously enough, in the abstract are looked upon from very mistaken ideas, as essentials to the *Magna Charta of liberty*. 'A man's own house is his castle,' and 'Every man has a right to do what he likes with his own.' These unpatriotic proverbs, taken in a practical sense, have injured man's constitution and damaged the framework upon which man's body has been built, by being applied to his own purposes by the ignorant, the designing, the selfish, the vicious, the miserly, and the indolent. Instead of being applied as protections against evil, they are opposed to true patriotism and the general welfare of the people, they have been used for the manufacture of evil, and the multiplication of foci from which disease has been spread, and life taken away from its owners; they are therefore quite antagonistic to the sacred feeling which ought to belong to human existence. They have shortened man's life, have weakened his intellect, have diminished his muscular power, and have sometimes caused his descendants to throw themselves under the Juggernaut car of an imaginary destiny, as if there was no escape from its consequences, no help for unhappy mortals from the sufferings of disease or the pains of the consequent death. The disciple of sanitary law has a better knowledge, he knows that man's destiny as to disease is to some extent in his own hands, unless his system has been tampered with by acts of his ancestors or the laches of himself or of his neighbour, or neglect of the State, in which cases he is somewhat hampered by mortgages which will have to be paid off by himself and his descendants. Notwithstanding this the sanitarian sees in the dim distance the realisation of his hopes, and with the Prophet Isaiah he believes that the days will come when 'There shall be no more an infant of days, nor an old man that has not filled his days, for the child shall die a hundred years old.' (Chap. 65, v. 20.) But 'that the sinner being a hundred years old shall

be accursed.' He sees an actual felicity in sanitation, as expressed by my predecessor in the address which he gave to the Congress at Glasgow, and which felicity may be looked upon as supernatural by the unlearned. The sanitarian sees the time when the knowledge of the sequence of God's laws shall be spread broadcast throughout the world, so that the consequences of a man's acts shall be as visible to himself and his friends as they are even now to the pathologist and the physician; and seeing the effect of those acts upon the frames of other men, he shall be careful to avoid corresponding effects by not committing the mistakes which may have led to their production in himself, in his descendants, or in his neighbours; for heredity in disease, or a deficiency in muscular and mental power is as certain to accrue to men as it is found to do among the lower animals of creation as regards form and other attributes. It may be in the early future, it will be some day, that persons will become ashamed of having to acknowledge themselves to be the subjects of complaints, which instead of, as now, exciting sympathy and condolence will be looked upon as blots upon the family scutcheon, and as such to be got rid of or hidden out of sight, and certainly not to be flaunted in the face of a more discerning world than is the present in matters of health. Men will then look out for their life-long companions from among those who are possessed of rude health, who belong to stocks enjoying long life, and from among the intellectually superior, from those with a pure blood and free from hereditary taint, such possessions being of more value than money or position, or even an evanescent beauty, a highly-strung temperament, or a hysterical sensitiveness, which is but too often the evidence of an inheritance from a gourmand, a drunkard, or a vicious man. We ought to look forward with pardonable desire to the time when defects in bodily health will be remedied, not as a man with one leg naturally remedies his defect by taking to a wooden one, but by using measures which shall remove the defect itself, and education of the young will then be on developmental principles. We find, in my own profession, a number of practitioners who fail to see this necessity, when they provide substitutes for a defective faculty in the young and growing youth, instead of rightly cultivating that defective faculty and bringing out its hitherto dormant powers. Spectacles for growing children, straps of all kinds in dress, high-heeled boots, and tightly-fitting corsets, will be sent to limbo, and foolish young people not allowed to go on in wrong lines.

I have used the term destiny with a motive. It is a term which has influenced millions who have surrendered themselves to its sway, and allowed themselves to be unresistingly carried on by the ever moving stream of time. They have been ignorant of the fact, or they have forgotten that the laws which govern matter can be directed by the will of man, and that the order of those laws can be changed by the power of that will. It has been forgotten that the will of man is in his own power so long as he holds the reins, but that if he surrenders those reins to others or throws them away because the exertion of that power is a trouble to him, because it is easier to go with the stream 'as one sheep follows another,' and 'one fool makes many,' he becomes the slave of a myth, and helps to add to the evil which is in the world, instead of

that evil and doing good to his own generation is especially the type of the hysterical nent of the present day, and which is sadly increase, being the inheritance which comes from the winebibbers of former times. If a stone in his hand he can throw it, or not at some object as he pleases, but, having it, the matter obeys the immutable laws along to matter, directed, it may be, by the man to some object, but, having left his power, is no longer under his control, and deflected from the path which he intended it and ricochet from the straight line, and strike, or even like the boomerang return and him who threw it. And as we read in the an'—

sted nail placed near the faithful compass
swing it from the truth, and wreck the argosy.
sanitarian believes that he can, by using
ans—

Turn the stream of Destiny,

Break the chain of strong necessity,
as Spencer sings)—

is tied to Jove's eternal seat:—(*Fairy Queen.*)

sanitarian does not believe in the permanence
litary evils.

not my intention to stay long in the distant
wander away in the cloudlands of psycho-
study, but I want you to bear with me whilst
at the time when knowledge belonged to
when the tendency of the human race in
life was to become depreciated in value by
d luxurious habits, by gluttony and other
self-indulgence, scarcely counteracted by
rival of the fittest; when writing was not
and tradition the principal mode of trans-
knowledge from one generation to another.
man had become a transgressor, and had
influences affect his frame. Those men who
re completely developed, and were wiser
ir fellows, marked the effect of the unknown
ked upon the fears of the weaker sort, and
the sequences of nature's laws to the super-
as if caused by the anger of the gods.
umed a power to intercede for the offenders,
to turn aside 'the bolt of Jupiter.' Know-
garding the true nature of the Supreme
as limited to few, and those few often used
nowledge for their own benefit. The fears of
le were used for the purpose of turning that
ge to profit. As a semi-civilisation again
established and a theology developed, the
of the gods became powerful agencies for
ersion of dogma both true and false. Some-
ogma was used for the promulgation of
d principles. This was the case when
power was in the hands of benevolent
; too often, despotism was simply a means
the masters of the place held power over
le, and it was only when a truly wise and
in like Solon or Moses was in the seat of
at advantage accrued to the people them-
stead of being used for the benefit of the
ometimes it happened that wise men studied
nesses of the people, and used those weak-
r the purpose of inculcating right principles,
n not uncommon among statesmen in our
rs. Faith in the supernatural among the

masses enabled them to do this by means of proverb. The promulgation of edicts took the form of religious dogma, and their authors worked upon either the fears or the faith of the people. These attempts to influence them were often made in times when pestilence was at work, and men's minds upset by the dread of an unknown future. Learned and benevolent men wished to bring them back to be influenced by those physical laws, the effects of which were altogether unknown to the masses. Dangerous and rapidly fatal diseases tended to strengthen the power of superstition among them. There was a good side in the means taken, but it had an evil tendency, and it was to that which Buckle refers in his 'History of Civilisation,' where he says, 'The real mischief was that it engendered in the mind associations which made the imagination predominate over the understanding, which infused into the people a spirit of reverence instead of a spirit of inquiry, and which encouraged a disposition to neglect the investigation of natural causes, and ascribe events to the operation of supernatural ones.' ('History of Civilisation,' Vol. I., fol. 115).

The effect of this mischief is well expressed by the Israelitish proverb referred to by the prophet Ezekiel, 'The fathers have eaten sour grapes, and the children's teeth are set on edge' (chap. 18, v. 2). In this proverb we have a distinct reference to hereditary tendencies, and to results which require much hard work to reverse; it applies to ourselves as well as to the ancient inhabitants of Palestine, and hereditary tendencies are some of the most difficult problems which the sanitarian has to deal with. I want to impress this fact upon the minds of my hearers, to point out that whilst cholera and fever, smallpox and scarlatina, diphtheria and erysipelas are undoubtedly immediately preventable diseases, yet prevention is not limited to those classes, but that insanity, tuberculous diseases such as consumption and scrofula, cancer, hysteria, and deformity of body and even of mind, as shown by passionate and vicious conduct, are also equally preventable, if we did but know how to proceed in order to stay their incidence. It was about this time that the real father of physic, and, I may say also of preventive medicine, made his appearance in the world, for it is only in recent years that we have realised how much was understood by Moses in this direction. Hippocrates owed his knowledge of physic in a great measure to reading the tablets which were put up in the temples of the gods. These tablets contained accounts of diseases from the effects of which certain individuals had recovered, and also an account of the means whereby the recovery had been promoted. Hippocrates lived about 500 years before the Christian Era; he is said to have died in his 100th year. He was a grand writer. The chapter upon the diet of healthy people may almost be taken as a string of proverbs, and, as such, was committed to memory and observed by his disciples; whilst the aphorisms which he formulated as to the conduct and treatment of diseases are considered to be, in many instances, distinctly true, even at the present day.

The aphorisms have been called a collection of oracles, and no doubt they did much to enable physicians to recognise the nature and to prognosticate the result in a variety of diseases, and to keep alive some medical information through the dark ages which succeeded the dispersion of the Jews.

He begins by stating that 'life is short, that art is long, opportunity fleeting, experience uncertain, and

judgment difficult.' He says also that a physician must cultivate philosophy if he is to succeed in his work, and he concludes that a physician who is a philosopher is equal to a god.

If we look into the oracular utterances which came from Delphi and other acknowledged fountains of supposed wisdom, we catch glimpses of these truths. Men did things which they were ordered to do by the oracles for the purpose of having themselves or their relations cured of their diseases—things which they would not have done if they had been advised to do them by their local physicians. The order to go and wash seven times in Jordan was, and is, usually too simple an instruction, unless it is accompanied by some mysterious utterances or some cabalistic performances which have an action upon the minds of those who were subjected to the effects. Simplicity was not believed and was not understood, and the most ancient proverbs or edicts with which we are acquainted were those which were made into religious observances. Those edicts which relate to sanitary law, and which were promulgated by Moses, are wonderful evidences of his clear insight into the causes of disease; the method by which infectious complaints were to be eradicated cannot be much improved upon by the arrangements recommended even by the intelligence of the present day, for they consisted of ventilation, of washing, of disinfection, and cremation. By making those performances into articles of faith, he was using a power to obtain his object which was more likely to be effectual than by any other then possible plan.

The travels of the Children of Israel in the wilderness furnish several instances of sanitary operations which have not been always put in their true light. We read that the Israelites could not drink the waters of Marah because they were bitter. Those waters were sweetened by the use of the branch of a tree growing in the neighbourhood. This action, which foreshadowed the custom of tea-drinking, is rightly made into a miracle in these later days. It pointed out a way by which water may be purified from its noxious qualities by infusing certain ingredients into it. It is a consolation to the tea-drinker of the present day that he not only takes for his usual diet 'the cup which cheers and not inebriates,' but he also takes into his internal economy a water which in all probability has been deprived of all noxious ingredients of the organic variety which it might contain when delivered to the housewife. Tea-drinking is a great preservative against cholera and fever. All the classes of disease which is spread by living germs or microbes in potable water, are removed: boiling it and then pouring it upon a material containing tannin is preterv certain to remove all evil from it which can set up infectious disease—for what the boiling does not effect the tannin will, and our tea-drinking friends need not be frightened by the onslaught of any who may happen to be put forward by a certain trading interest, and who at this present day are loudly crying out, 'Great is Diana of the Ephesians.'

Another custom which had its origin in Arabia and Egypt, and which was instituted by Moses as an edict to be religiously observed, was the burning of incense. They offered to God a part of that which they held to be most precious, and at the same time fumigated the wearing apparel of the worshippers, and to some extent the air itself, and by so doing diminished the chances of the evil likely to arise from the crowded assemblies, which

were then held at stated times, for the purpose of religious worship. Plutarch mentions Egyptians offered incense to the sun; res morning, myrrh at noon, and a compou kypi at sunset. Moses, probably knowing beneficial results which followed this ceremony having observed that illness resulted when not performed, when he resided in Egypt it a part of Hebrew worship, and thus secured performance whenever religious ceremonies undertaken. Its continuance in the Middle Ages by the Christian churches was a necessity of times, and assisted to produce a certain ozonised atmosphere which diminished the of the spread of infection among the assembled shippers. This was done in a pleasant manner covered up a noisome smell by one more able. The old proverb hath it 'that the garlic takes away the smell of dunghills,' and thus assisted to promote the ventilation of apartments, by which all kinds of miasma lessened in amount, and the epidemics of those ages diminished in frequency and in intensity. The great evil was lessened by a simple plan, and a religious ceremony was sure to be performed but which as a sanitary precaution would have no chance of observance when infectious diseases not present. Yet the time to prevent disease before it is grown up in intensity. The detection of the first germ or seed is of the greatest importance, and incensing therefore was in the middle ages, a necessary precaution for the priests even more than for that of the people. There is a proverb well known to the people which especially applies to sanitary work, viz., 'One year's seeding, seven years' growing.' This proverb is a true expression of the value of allowing a single case of infectious disease to grow up among the people. Illustrating the value by a reference to small ones, I would point all here the great importance of early intervention being afforded of the presence of infectious diseases in the homes of the poor, so that incensing performed at the right time, and by the right person. A single case attacked with vigour, by incensing and other agencies, which ought to be immediately available among the people, may be the means of preventing the spread of a serious epidemic. A single weed rooted up by the gardener at seed time, saves him work of the same amount seven years to come.

Incensing may, or may not, be carried on in sacred services, but it must be done immediately in all cases of infectious disease by the local authorities, and I urge the people of Dublin, therefore, that it be carried out. By incensing you will understand that I mean disinfecting the wearing apparel by a judicious use of proper disinfectants.

You have an organisation in Dublin capable of good work in this direction. The Sanitary Association, with scarcely 200 members although it is in a city of 250,000 people, has for the past twelve years been at work in trying to popularise sanitary truths, with a moderate amount of support: let me urge upon you to help it in its similar societies. Shakespeare says truly—

The web of our life is of a mingled yarn
Good and ill together.

(*All's Well that Ends Well*, Act iv.)

No one here present knows how soon he

down by mischief from one of the byes of Dublin which that Society might have pre- if all those able to do it had joined its ranks, en support to its organisation. You may onfidence in its working; with but small t has already done much good. Help it by ; to create a true public opinion upon sani- tters in general, and thereby to save many d increase the welfare of the community.

ups the most remarkable of all ancient pro- e those which refer to strong drink. Moses its use when the priests went into the House and he states (when charging the Israelites e left them) that they had not tasted wine g drink for forty years, and he commends r their abstinence; though it is quite clear er parts of the context that he did not re- e use of wine as a sin for those who wished ge in the luxury. He did not prohibit it er, except to certain persons and at certain The Rechabites were commended in the the Prophet Isaiah, more because they had eir father's commandment than simply for stinence. The wise are warned against its ie Book of Proverbs, and its effects are very put before the readers of that wonderful reflections and sage counsels by one who y knew all about its effects.

however, not until the days of Mahomet meet with a general acceptance of absti- om wine and strong drink by great masses le. I have very little doubt myself but homet's wonderful career was much influ- y his temperance maxims. By making ce from wine and strong drink a part of his tenets he was giving a proof of his intel- uperiority over those around him, and laying dation for his future greatness.

ad observed the helplessness of men when cups, and the weakness of their mental ie day after a debauch. He determined to blow at such mental degradation by making ition an impossible one among his lieutenants oetes. In consequence of the dogma of ce he and his followers became the superiors ordes of Arabia, and eventually a terror to e civilised but less temperate nations of the vov, or Roman world. Mahomet with his one God—whom he regarded as a Being , benevolent, and just—and having the f total abstinence on his shield, was able to the face of the moral world and do much to from the degradation into which it had

the sixth and seventh centuries, in conse- of the luxury, the vice, and the intemperance alled civilisation. If he had abjured the he sword; if he had stuck to his articles and not done evil in order that good ome, and had not forced his views upon the y the pouring out of human blood; if he sted upon the sacredness of human life under umstances—Mahomedanism might have e of the greatest blessings the world had sessed, and it would have prepared the way itianity in a most effectual manner. Clean- as a part of the Prophet's creed, and to this s observed in a way by the sons of Islam, unfortunately it is not associated with a be- ffection. The habit of cleanliness is said

Christians to be next to godliness, though ly forgotten even in Christian schools and

among Christian communities; but we may be cer- tain that no creed, no dogma, either religious or political, which does not inculcate the sacredness of human life can long continue in the future to hold the mastery over the minds of men.

No other country or people except Mahomedan races have taken abstinence as one of their tenets until the days of Father Mathew. If either Celt or Saxon, or both, had done it—if the colonising power which belongs to both had been strengthened by Mahomet's tenet of sobriety—what a different world we should have around us! The bitter cries which go up from the banks of the Thames, the Clyde, and the Liffey, and from a greater part of this beautiful island, as well as from all parts of the world to which the trade of the United Kingdom extends, would have been shorn of much of their bitterness and intensity. Father Mathew's work was defective, and therefore evanescent, for it was mis- understood. He clearly enough put before the people that it was the drink which led men to do wrong, it was the drink which led men to starve their families and ruin their health, and pour out their blood upon the earth; but it was not the de- testation of their crimes which caused men to be abstainers, but because it led men to miss their mark, as was said when a total abstinence lecturer was asking an Irish audience as to the evils which the drink had done. 'It led men (said the lec- turer) to shoot at their landlords,' and, said a voice in the crowd, 'To miss 'em!' It was not the dis- gust for the degradation caused by drink which led to Father Mathew's temporary success; but it was a desire to save money, which was used for other and unsatisfactory purposes, and as a consequence the movement has not been permanent. Is it not time to resuscitate Father Mathew's noble work upon a firmer basis—viz., one connected with the sacred character of human life? and to prevent that reflection (disgraceful to him who wrote it) which appeared the other day in the London *Times*—'That people generally would think it better that an Irishman should be addicted to whisky even in excess than that he should be skilful and successful in taking aim at a landlord from behind a hedge.'

There is another sanitary work intimately connected with religious tenet, which I cannot pass by without referring to—viz., that of 'fasting.' Those were clear-headed observant men who instituted a fish dinner on Friday. The daily use of meat has its disadvantages, and sets up evils of a serious kind connected with gluttony, which the fathers of the Roman Catholic Church turned to good account when they made abstinence from meat on Friday a part of their religious duty. Fresh fish contains much of that material which renovates nerve matter, and assists to prevent its decay, whilst an interval of rest from strong meat enables the brain to become clearer for its Sunday work by giving time to the blood to be purified from excess of nitrogenous food. All honour to those men who used their knowledge to such good and such unselfish purposes. If all dogma had such foundations it would have been much better for the interests of the human race. But, at the present day (as well as in former times), it is too often used for selfish purposes, and for personal aggrandisement. Sanitary knowledge, however, is forcing itself upon the attention of all parties in the State; politicians are ready to take hold of it and use its arguments in their favour, if it will secure

them a few votes at a given election ; but as soon as the candidate obtains a seat in the House of Commons, or in any other elected body, the majority of sanitary reformers forget their pledges, and allow the evils which they promised to eradicate to go on eating into the vitals of the people.

Can we not do something to change this plan ? Is it not time for politicians to shake hands over the measures which are called for by sanitarians because they influence the health of the people ? Why should not such measures be taken out of the range of politics, and put before the House and our town councils as non-political measures, to be judged upon their merits ? Why should not Sanitary Bills be backed by the names of men on both sides of the House, although they are Government measures ? Departmental Bills of this kind ought not to be impeded, blocked, or thrown out, simply because they have been introduced by a Liberal or a Conservative Secretary of State, as the case may be. The unpatriotic conduct of political men is much to be deplored, for it appears to those who watch the game from an unpolitical standpoint that place is of more importance than progress, and measures which are good in themselves must be opposed because they are brought in by the Government of the day. Ireland has suffered more for this action than has either of the sister countries, and the effrontery with which both political parties have been bidding in past years for the Irish vote, by pretending to be benevolent, has been most marked in offering to do something for Ireland, when they ought to have insisted upon the work, if it was necessary, being done by Ireland herself. This conduct has assisted to breed up a pauperised class, just as it has always done on the other side of the water, in those towns which have been cursed by a mistaken benevolence, which has so reduced a portion of the population as to lead them to be unable to assist themselves. Benevolence misapplied, as all political benevolence is sure to be, ruins the independence of a people, and tends to destroy that self-respect which can alone raise a nation to her proper place in the universe. Can we hope for much improvement in the health and morals of the people, either here or across the Channel, whilst such a plan is in the ascendant ?

I am not arguing in favour of compulsion in sanitary work, I mean governmental compulsion. I do not believe in the use of force for such purposes by a paternal government ; but I would urge that whilst regarding 'every man's house as his castle,' in which he may do as he likes with himself, he has no right to crowd it up with inmates in excess of its capacity. There are limits in the power of so many cubic feet of air to sustain life in good health. When a man asserts his right to cram his house with too many occupants, the local authority, that is, your representatives on your local council, should be able and willing to set the proverb aside, and say to that man, you may smother yourself if you like, but you shall not smother your wife and family ; you shall not decoy your neighbour in as a lodger, and deprive him of his health, and his country of his value as an operative ! Overcrowding is at work in Dublin as well as elsewhere, and the great mortality which arises from this cause is produced by the desire to get rich at the expense of the life blood of the nation. No one can read the report of our President and his colleague regarding the sewerage and drainage of Dublin without being satisfied with its truth. 'There is more money got by ill means than by good acts ;'

but the heaping together of money by men who crowd their hovels or their acres with more of their fellow creatures than the area can fairly accommodate is one of the most debasing and brutal kinds of money getting, which should be put down by the strong arm of the law, put in force by public opinion. The municipal council chamber should vie with Imperial authority in crushing this canker, which strikes at the vitals of the commonwealth ; and it becomes the duty of the State to see that the houses provided for the poor are not overcrowded, and are not imperfectly ventilated, that they can be kept clean and are well provided with that important necessary of life, pure water, and that waste and impurity can be rapidly removed from among the occupants. By its being the duty of the State, I mean the duty of the local authority armed with power conferred by the Imperial Government. Is Dublin doing her duty in this respect ; are the inhabitants of this great city alive to the fact that the expenditure of money by the local authority will be repaid to them tenfold in the better health of her people ? 'There is that scattereth and yet increaseth, and there is that which withholdeth more than is meet, but it tendeth to poverty.' (Prov. XI., v. 24).

I wish I could have this proverb written in letters of gold in every council chamber in the kingdom ; it ought to be before every man aspiring to be an alderman or councillor in every corporation, and as much in Dublin as anywhere else. With a death-rate of 28 or 29 in the 1,000 it is evident to every sanitary reformer that someone is responsible 'for withholding more than is meet' in this place.

The working men of Dublin are a power ; here they can elect a majority of the representatives in the Council. Do they know what is meant by a death-rate ? The town I reside in used to have a death-rate of 26 in the 1,000, it is now 16. That is, the lives of ten persons out of every 1,000 are preserved to their relatives who would, but for sanitary expenditure by the local authority and by private persons, be numbered with the majority every year. Let us suppose that the death-rate of Dublin were reduced from 28 to 16, it would mean that the funerals in the course of the year would be diminished by more than 3,000, a serious matter for the undertakers, still, a trifle worth preventing. But it would also mean much more than this ; for every death there are twenty cases of sickness, and if there are 3,000 fewer deaths, there would also be 60,000 fewer cases of sickness among the people every year. Let me ask the members of the benefit societies who happen to be present whether they can realise this fact, whether they can understand that for every death prevented there are twenty cases of sickness also prevented. Let us suppose that 20,000 of the working men of Dublin belong to benefit societies. They have to pay in weekly or monthly payments sufficient to provide for a sick fund ; the greater the sickness, the more they have to provide from their earnings to meet it. If sickness is permanently reduced they will be able to permanently reduce their payments on this account. The 20,000 members will at present death-rates average at least ten days' illness for each member in every year. If you diminish the death-rate you will also diminish the sick pay (which has to be provided), and reduce it to an average of six days per year. If you bring it down to be equal to that of the town in which I reside, your 20,000 members will be saved from having to provide for 80,000 sick days' pay in each

ear. They will also have in their pockets the wages which they will have been able to earn in work, instead of the half-pay which sick-pay provides, and they will not have had to contribute so many levies for the extra funerals which the higher death-rate has evoked upon them.

Let me ask the working men now present if the proverb I have quoted is not one specially intended for their benefit, and that for their own sakes, as well as for that of their wives and families, they should take care to send men into the municipal council who will not be afraid of expenditure which is likely to be of the kind 'that scattereth and yet increaseth.'

That they should consider these local questions as far greater importance than those political questions which but too often lead men to elect representatives because they belong to a particular political party, instead of being wise and thoughtful sanitary reformers. Party politics ought not to enter into the consideration of our local representatives, and any council elected on such lines will not be the best council for sanitary work.

Ask those who wish to represent you if they will take measures to prevent overcrowding among you; if they will take care that every house is provided with a supply of pure water at the lowest possible cost, or at the cost of the owner, and that there are houses which are fit for the poor to live in; if they will take care that waste and refuse be removed from your midst before it has time to set up mischiefs, similar to those which are now making themselves felt in the stinking towns of Southern France and Italy; ask them to insist upon the Liffey being restored to its pristine character, and not leave it any longer to be a *cloaca maxima*, a great sewer, and as such a disgrace to the fairest city in the kingdom. It is curious to my mind to see how carefully some of our public men—local as well as imperial—seem to be wise in their own eyes, and yet fail to see that they are like the foolish virgins of Scripture, though the inference will force itself upon the mind of the thoughtful man that they only represent the public ideas. We are sending all over the world for phosphates and artificial manures, we are paying almost famine prices for meat and milk, whilst the very materials which should be turned into those articles are sent into the sea as food for fishes, which we don't catch, or, if they are caught, are not consumed, or are used for impeding the navigation into the docks and harbours of our great cities, or poisoning the inhabitants of our inland towns, or are destroyed as valueless. This observation applies to Glasgow, to Belfast, and to London as well as to Dublin. The town in which I reside does differently; the sewage is not sent into the sea, but it is returned to the land, as all sewage ought to be; it benefits the nation by growing green crops. Every acre under sewage cultivation can grow five times as much herbage as it did before it was so cultivated. There is five times as much meat and milk raised on that land as formerly used to be the case, and by so much has the tendency to meat famine been reduced.

If all the sewage of London had been treated in a similar way, 60,000 head of cattle might have been raised and fed each year in addition to our usual home stock. This addition would have made us by so much the less dependent upon foreigners for our meat supply, and have made a larger market for the young stock of the sister-country. The inhabitants

of London prefer to throw their refuse into the River Thames, to poison their neighbours lower down the stream, to damage their harbour, and so prepare for the time when the shipping trade of London will become impossible. The question is raised by narrow utilitarians as to whether sewage utilisation will pay. Patentees and company mongers join the cry, and prevent the progress of this great work.

I have so often urged that it is not a question as to the payment for this or that particular year, or this or that particular outlay, as that in the end a national benefit results which will pay ten times over more handsomely than it is possible for the River Thames or the Liffey to do by being transformed into an immense sewer. Sewage irrigation has outlived the outcry made against it that it was a sanitary danger; it has been shown most conclusively that it is perfectly free from such evil. It has been shown that the produce from it can vie with any produce as to its goodness and commercial value, and that wherever there are people to produce sewage, there is a market for that produce. More than 100,000,000 gallons of water are daily abstracted from the collecting grounds of the Upper Thames; they are used in washing the people and flushing away their refuse into the drains of London, and are then, with the collected mass of filth, sent down to Crossness and Barking to poison the lower reaches of the river, and gradually produce a state of things which will make the future sanitary history of that river somewhat similar to that which now belongs to the Pontine Marshes or the Deltas of the great rivers of India, whilst the bed of the Thames above the metropolis is being deprived of its proper water from the deep springs which ought to supply it.

It is now a question of money, but in the end it will be a question of vital importance to London. It is one which has no political significance like a Turkish or an Egyptian loan, and there is no palm oil belonging to its promotion. The 100,000,000 gallons of water fouled by the filth of London ought to be returned to the land from whence the water came, and ought to be again filtered through the Chalk Hills, the Woking and other sand beds, or the barren acres of Surrey, Hants, Berks, and Oxfordshire, by which tens of thousands of cattle might be nourished, and millions of gallons of milk provided for the teeming population of the great metropolis of the Empire, and so render them less liable to the incidence of that meat famine which will come whenever the foreign markets are closed to our merchants and shippers. Those acres are not now worth 5s. per annum. If they were supplied with the sewage of London, they would be agriculturally worth at least 5l. per annum, but an 'Englishman's house is his castle'; his country may want meat and milk, but it must not grow these articles near to his broad acres, though it contains his countrymen's diet, and may be the means of saving them from the chances of starvation in some future time. The ideal damage which such a use is supposed to produce is enough to stop a national benefit, and prevent the carrying out of those works which would transfer the barren ranges of hills to the north-west and south-west of London into fruitful fields, and fill the River Thames in the driest season with a healthy flood of waters. The sanitarian has a duty to perform in addition to the saving of life; he must take care to prevent his work from bringing about a result which will come if an increasing people be not properly fed. He is able to show you that Lord

Palmerston's saying is perfectly true, viz., that 'filth is but matter in the wrong place, and that if it be transferred in a proper form, and in a proper manner, to its proper place, it will provide food for the people.' Yet we allow it to go to waste or we promote measures to render it valueless, and so misuse our noiseless highways in a way which must render them in the early future as noisome as the Tiber became to the inhabitants of ancient Rome.

I would urge upon the inhabitants of this beautiful city that they rest not until the sewage is taken out of the Liffey, and sent to its proper destination, viz., to the land which wants it; that they rest not until the inhabitants in their close quarters have more breathing space among them. That water should be available for every boy or girl, as well as every man and woman wanting it, without stint, and that the pure air from your native hills shall not be fouled with noisome impurities as soon as it reaches the precincts of your city. You will then have paved the way by which health may be secured, and a happy and long life be yours, for 'national health is national wealth.' Recollect, however, that 'cleansing a blot with blotted fingers maketh a greater.' The first principle of sanitary work must be carried out in the individual house. The householder must desire a healthy home, and to have it he must purify the governing body from the presence of those who prefer an unhealthy people.

VENTILATION OF CHURCHES.—Messrs. Robert Boyle & Son, 64 Holborn Viaduct and Glasgow, have recently applied their Patent Self-acting Air Pump Ventilator and System of Ventilation to the following churches:—St. Giles's Church, Soho; Palmerston Road Church, E.; Congregational Church, Burdett Road, E.; New Church, Hornsey Road; Wesleyan Chapel, Gillespie Road, N.; Baptist Chapel, Plymouth; Independent Chapel, Ilfracombe; Congregational Church, Brighton; Wesleyan Chapel, Comb Morten, Devon; Christ Church, Murfield; Mount Zion Chapel, Sheffield; Strood Church, Kent; New Methodist Chapel, Colridge, Burslem; Carrs Lane Chapel, Birmingham; Greystones Parish Church, County Wicklow; St. Paul's Church, Bedford. Messrs. Boyle have also just completed the ventilation of St. Matthias Church, Earls Court, for Mr. Arthur W. Blomfield, architect, for whom they have also recently ventilated the chapel of Emmanuel College, Cambridge; St. John's Church, St. Leonards; and St. Michael's Church, Paddington. Plans have also been furnished for the ventilation of St. Mary Redcliffe, Bristol. Messrs. Boyle have received the following valuable testimonial from Mr. Blomfield, 6 Montague Place, Montague Square:—'I have used the Air Pump Ventilator of Messrs. Robert Boyle & Son with satisfactory results. I believe the system to be a sound and good one, and capable of varied application with success.—(Signed) ARTHUR W. BLOMFIELD.'

THE *Gazette des Architectes* announces that it is proposed to institute in Paris a special 'service d'hygiène municipale,' to unite under the control of one chief all the services concerned in the sanitation of Paris. These include the management of the water supply, of the sewers, the overseeing of 'ordures ménagères,' and of the cleansing of the public streets, the cleansing of brooks and of the street channels, the sanitary treatment of the Seine, the control of all dangerous or insanitary structures, the medical inspection of schools, of lodging-houses, and of the municipal laboratory, &c. This functionary, who is to have the title of *sous-directeur*, will certainly have enough to do. With us he would probably be Minister of Health.

'ISOLATION versus VENTILATION'

By H. PERCY BOULNOIS, M.Inst.C.

ANALOGOUS to the question of the disposal of sewage is that of the danger arising from passes along the public sewers; and therefore, of this paper is to open up upon the somewhat vexed points as to methods at present known for the solution of our sewers, as to what methods have been attempted, and whether these attempts have been successful. An endeavour will be shown that the modern practice of opening centres of the streets is unsatisfactory and sary, and that it is a far more important measure to isolate the house from the means of simple and effective traps, than these openings in the sewer, and that if this is perfected the sewer ought to be completely out of smell as well as out of sight, now unfortunately far from being the case.

The present system of ventilation seems to have originated about the year 1830, when griet complaints were constantly made by the inhab the City of London that great stenches at the gulley-pits at the sides of the roads; th being trapped, caused the foul air to pass the untrapped house-drains into the houses, and the remedy proved more unsan the original complaint. The cure that immediately suggested itself was the relief of the foul air by making openings in the sewer, carrying shafts to the centres of way, and protecting these shafts with iron a practice which has been steadily copied year 1840.

These openings, however, were speedily to be all that was necessary, for in spite of foul air still entered the houses through the drains, and the object had not at all been. Consequently traps were introduced in break the continuity of the house-drain; now old-fashioned brick pit, with slate tongue, called a Mason's trap, and then it was introduced, the seal was deepened, traps were inserted and flaps were placed ferent parts of the system in order to isolation of the house. It is only of qu date, however, that the real secret of separation, or isolation of the house, effectual, and this was done gradually—cascade action in the trap was introduced, the important addition was made of le soil-pipe open for ventilation. This was by cutting off all connections between the waste-pipes from sinks, baths, &c., and causing them to empty on to gr other methods; and then the pneumatic was devised, by which fresh air is introduced house side of the trap, and a current is stantly passing through the house-drain, the help of the deep trap entirely cuts off from the common enemy, the public renders it as completely isolated as modern science can effect.

Owing to the varying level of the fluid in sewer, some escape must be provided contained in it, otherwise one or more of drain traps would be unsealed by the air as

* Read at the Congress of the Sanitary Institute of G at Dublin, on Oct. 2, 1884.

ose, and this can easily be effected by carrying a shaft of about 6 inches in diameter from the crown of the sewer near its highest level to some convenient and safe height against an adjoining building. One such shaft would be sufficient for nearly any ordinary street sewer to relieve the pressure upon the traps until long after the connection of the house-drain with the sewer was below the level of the sewage, and this would meet the requirements of the most violent rainstorm, and prevent the unsealing of the deep sealed traps. Should, however, a trap become unsealed, the open character of the house-drain and the traps of the water-closets, which should be of some simple wash-out pattern, would quite prevent the chance of entry of any of the foul sewer air into the house, and thus the sewer ventilation, as it is called, becomes perfectly unnecessary.

Before proceeding further to discuss the question, it will be interesting to observe the following chronological list of different methods which have from time to time been suggested or actually attempted, not only for the purpose of ventilating sewers, but also for processes of destruction, retention, or harmless conversion of the different gases contained in the sewers.

The list is as follows :—

1840. Open shafts, as already described, were first introduced.

1848 to 1853. Captain Shrapnel made a suggestion that high cast-iron cylinders should be constructed over the sewers in which furnaces should be placed to consume the gases.

Messrs. Warr and Armstrong proposed to build domes over the sewers from which pipes should conduct the foul air to a central gas-holder, whence after purification it should be distributed for street lighting. Another proposal, about the same date, was that sewers should be hermetically closed except at one point, where an air-pump would extract the foul air and drive it through fire or a solution of chloride of lime. A suggestion was also made that coke factories should be established near the lines of sewers, and the gases therefrom passed through the ovens.

1854. Sir Joseph Bazalgette in London successfully ventilated a sewer on the south side of the Thames by carrying a pipe from the crown of the sewer into the tall chimneys of two factories. In another case, however, in Friar Street, where this was again attempted, an explosion occurred which led to the abandonment of experiments in this direction for a time. Mr. Gurney in the same year tried the effect of steam jets introduced into a sewer, but without any good result.

1855. Mr. Mumby proposed that the gas lamp-posts or columns at the sides of the streets should be used as sewer ventilators; but as these are only lighted at night Mr. Robins suggested that the posts should have trays filled with disinfectants placed in them, over which the sewer air should pass.

1856. Shafts were erected at the ends of streets connected with the dead ends of sewers, and carried up the gable ends of houses.

Furnaces in connection with these shafts were also recommended.

1858. Mr. John Chisholm tried the effect of electrical or galvanic action upon the air in sewers, but without beneficial result.

1866. Trays filled with charcoal were introduced by Sir Joseph Bazalgette and others into the ventilating shafts.

1870. Sir Joseph Bazalgette successfully neutralised the foul emanations from a sewer by the introduction of trays filled with sulphurous acids.

1872. Screens or flaps were placed in sewers to regulate the currents of air in them. Messrs. Johnson and Hill proposed that ventilation should be effected by connecting all the house-drains with the chimney-flues. Mr. Miller suggested that the smoke from chimneys should be drawn into the sewers for the purpose of purifying the bad air in them, and at the same time settle the London fog question satisfactorily.

1873. General Scott introduced lime into a main sewer, with the result, to use his own words, that 'the main sewer was perfectly freed from stinking sewer gases.'

Dr. Keates devised an apparatus for subjecting the foul air to the action of chlorine gas.

1875. Mr. Parker, the surveyor of Poplar, England, patented a method by which air was to be forced into the sewer by the action of the wind impinging upon a cowl.

Sir Joseph Bazalgette erected a ventilating chimney, 60 feet in height, with a furnace burning coke, when, to use his words, 'It was found that about 1 per cent. of the sulphur was given off by the coke, and acted as an efficient disinfectant.'

Mr. E. Rumbold originated a method for passing the foul air through a spray of water introduced on all sides of the ventilating shaft.

In the same year, being struck by the absence of smell in an old sewer, in which quantities of stagnant sewage were giving off gases of decomposition, I came to the conclusion that this absence of smell arose from defects in the crown of the sewer, which allowed the foul air to be absorbed in the earth which covered the sewer. The outcome of this observation was the invention by me of what I have designated 'The Sewer-gas Annihilator,' the principle of which is based upon the well-known fact that earth has a powerful action in absorbing and deodorising any noxious gases or emanations arising from matters undergoing decomposition.

In 1882 Mr. Read, the surveyor of Gloucester, suggested that all house-drains should be used as up-cast shafts to ventilate the main sewers, for he argued that as the sewer was used for the benefit of owners of house property, so should they contribute to the ventilation.

Mr. Harrington, the Mayor of Ryde, Isle of Wight, proposed in the same year a system by which air should be forced into the sewers by shafts furnished with cowls, his system being somewhat similar to that proposed by Mr. Parker in 1875, and already described. (See SANITARY RECORD for Nov. 15, 1883, p. 250.)

1883. Mr. Rowan suggested the sub-division of the sewers into sections, so as to ensure their thorough ventilation, 'each exhaustor drawing from the inlets on either side of it, and the inlets consequently delivering air to the sewer in both directions.' The abstractor to be of special construction, and to perform a double function—abstract the sewer air, and burn and destroy any organic matters or germs contained in it, the sewer air being made to pass through a number of small tubes heated by a gas jet. Mr. Rowan claims that not only is heat thus made to destroy the danger in sewers, but that fresh air is also admitted into them—the two most important points in connection with this question.

With regard to the systems of ventilation at present in vogue, that of open gratings in the centre of the streets is the most general. By a return recently published, it is found that out of sixty-six important towns in England, fifty-five of them adopt this system, and it certainly has the merit of being economical and simple, both in construction and maintenance, and it relieves the sewer from any air-pressure when its contents are running at a higher level than usual.

The system, however, does not comply with sect. 19 of the Public Health Act, 1875, which states that sewers shall be ventilated 'so as not to be a nuisance or injurious to health.' The street gratings are an undoubted nuisance, as they unload their foul air under the level of our noses, and it is possible they may be injurious to health: for although, on being liberated, the dangerous qualities of the sewer air are said to be diluted, dispersed, and rendered harmless and innocuous, it has never been satisfactorily proved that the atmosphere kills the disease germ, should he be there lurking, or, if it does kill him, how long is taken in the process? certainly not the short time elapsing on the journey between the grating and the footpath. There is no doubt that excessive dilution lessens the risk of contagion, but the system does not seem successful unless immunity from nuisance and disease can be assured.

It is said that where the sewers are in a good condition no nuisance arises from the ventilators; if this is so, the question may fairly be asked if they are of any use in such cases, and whether the perfect sewer is not just as perfect without them. Advocates of the system state that it is impossible to have too many openings, and thus open sewers would, no doubt, be the most desirable. The town of Leeds is frequently held up as a model in respect of the ventilation of its sewers; let us compare its death-rate with that of the town of Bristol, where not a single sewer ventilator exists:—

Leeds has a population of 15·2 per acre; Bristol has a population of 46·5 per acre; Leeds had a death-rate for 1883 of 23·30; Bristol had a death-rate for 1883 of 17·80. Of this death-rate those arising from the principal zymotic diseases were, as regards Leeds, 4·0 per 1,000, as regards Bristol 1·1 per 1,000.

The Commissioners of Sewers for the City of London have for a long time felt that the open gratings were not all that could be wished, and have consequently, quite recently, passed a resolution to enable their officers to treat with builders and owners of property for the purpose of erecting shafts, either in the walls of, or against new and existing buildings.

Open shafts carried up to safe heights certainly have many advantages over the foul smelling gratings in the centres of the streets; and the fashionable watering-place, Scarborough, has, I believe, the whole of its sewers ventilated in this manner; there are, however, some objections to this system, which may be summarised as follows:—

The want of fresh-air inlets, the expense, and the difficulty in obtaining permission to erect the shafts just at the points where they are required, and of course, in new streets that are being sewered, and other localities, there are no houses against which they can be fixed.

The fresh air inlets, as by Mr. Parker's and Mr. Harrington's systems, are an improvement, but they involve that great bugbear to the ratepayer, extra

cost; and there would no doubt be some objection raised to obstructions of the kind being placed against the sides of the streets; otherwise systems have much to recommend them.

The use of the rain-water pipes for sewer ventilation has often been justly condemned; they are to act as outlets during rain, but, on the contrary, they carry more air into the sewer; and, from their position and possibly bad jointing, are said to be dangerous. The town of Carlisle, however, ventilates its sewers in this manner, there being upwards of 2,150 rain-water pipes in direct communication with the sewers.

Charcoal trays are too well known to require comment.

Large hollow lamp-columns have many recommendations, but they cannot be extensively used unless the gas is constantly kept burning, though but of little use.

Pipes carried from the sewer into neighbouring chimney shafts or under furnace fire bars are a system that is gradually extending and has much to recommend it; it is well known that the most effective destroyer of all forms of germinal life or matter at all stages of their development is heat, and it is probable that in this direction scientific perfection of sewers will be eventually attempted. In Leicester there are upwards of thirty chimney shafts which answer satisfactorily.

The early dangers encountered by explosion in connection with this system seem to have been entirely accidental, and probably arose from the admittance of coal gas into the sewers from drains, and no recurrence seems to have taken place for many years.

With regard to special lofty shafts fitted with furnaces, these seem to be effectual under certain conditions, as, for instance, upon main intercepting or outfall sewers where there are few openings. The case of Brighton, where a large shaft with a furnace has been in successful operation for many years; but Sir Joseph Bazalgette proved years ago, and subsequent experiments have confirmed his opinion, that the effect of such shafts upon the general system of sewers would be ineffectual, as the tendency of the exhaust pipe by such a furnace is only to draw in sufficient air to feed it from the nearest opening.

In conclusion, I wish to lay the following before you, in order that they may be discussed.

Is the present system of open sewer ventilation the centres of the streets satisfactory? Is it in compliance with the requirements of the Public Health Act, 1875?

Do any of the systems which have been enumerated fulfil these conditions?

If the drains of all buildings are properly and efficiently trapped, ventilated, and the buildings isolated from the sewer, is any ventilation but a few relief pressure shafts necessary?

Should not this isolation of the house be made legally compulsory?

AMONGST the most recent applications of the Waterspray system of ventilating, heating, and lighting are the Walker Memorial Schools, Leicester, Mr. Consulting Rooms, Harley Street, the New Mission, Duntshill, Wandsworth, the New Baptist Chapel, St. John's Church, Waterloo Bridge Road, Nova Scotia Mills, Blackburn; and St. Mary's, Grassencia, Liverpool.

COLLECTION AND DISPOSAL OF HOUSE REFUSE.*

By W. EASSIE, C.E.

It has not been able to find any statistics giving like the exact analysis of the various materials which go to make up ordinary house refuse, but in Paris, thrown into the dustbin; but whilst Paris is managed in the ordinary way by ragpickers, in London the present municipal cart system was introduced. In Paris, Paris possessed about 500 rag merchants, employed each some half-dozen rag-pickers, so that it was to collect and sort the house refuse outside the houses. Out of every 136 lbs. of refuse collected in Paris, the following gives the value of what can be sold:—Paper, 40 lbs.; rags, 20 lbs.; and wool, 18 lbs.; bones, 28 lbs.; glass, 10 lbs.; waste cloth, dressmakers' scraps, thread, &c., 10 lbs.; iron, brass, and lead, meat tins, and capsules, 13 lbs.; old shoes, leather, &c., 6 lbs.; india-rubber, and broken toys, 4 lbs.

London will not give us any fair estimate of the value of house refuse, because, although the above represents the weight of the assorted articles taken out of the dust, and does not include household refuse from our country, where coal is so abundantly used, it must be remembered that the increment of refuse in London would be very largely increased. In London there would be a much heavier item for refuse than in Paris, for thenware, for old blacking-pots, ink-bottles, &c. In the analysis of the Parisian refuse mentioned articles which were of value to the ragpickers, and there must of course be a great deal of waste thrown away there; but, taking into account the inhabitants of the two cities, Paris and London, there could be no question that in the aggregate the quantity yielded in London would preponderate. One thing I dare say about, and it is that London would beat Paris in a show of empty space and medicine bottles. Some time ago Mr. Dr. Roth, of Dresden, the eminent State Sanitary Officer, put himself under my care, that I might see, among other things, how we managed the refuse of our house and street refuse. I took him to the City of London, which is the only completed system I know of, and we were most amused to find that the vast number of full medicine bottles had never been emptied, as compared with the number of bottles which had been thrown into the

the bells attached to which in some towns inform the householder that the dustman is passing, and that his portable receptacle of dust and other refuse, which he has previously placed in a handy spot, will be carted away on pointing it out. Or if dustbins are the rule, the letter D placed in the window will indicate to him that the bin is full and must be emptied. It is not often that the dustman calls without invitation, and more often he requires the solace of a small honorarium, especially if there is any garden refuse, wall plaster, old paper-hangings, greenhouse clinkers, or extraneous matter of that kind, which according to most authorities the local board are not expected to remove. Only ashes, peelings, kitchen vegetable leaves, and inside house refuse is bargained for.

All sanitarians, medical or engineering, are of opinion that something better than our present system of dust-bin storage might be devised. Not that the dust-bin is outrageously evil in its conception, but rather that it is abominably treated. It should not contain vegetable and animal matter commingled, rendering the neighbourhood, during the upheaving and emptying of the fermenting matter, noisome with dangerous gases, and not only that, but causing the dust-cart to give off these foul gases during their progress through the streets.

Undoubtedly, the dust-bin could be made portable, and the contents kept automatically disinfected every time the lid was raised, but the chief amelioration would result from a constant burning of the vegetable refuse in the kitchen fire. This, however, would require almost to be made incumbent upon the householder by some by-law, which is hardly likely to be enacted. One word more about these fixed dust-bins and I have done with them. They are seldom water-tight, and mostly placed against the wall of the house, and allow the liquids to drain under the floors and cause a rising dampness in the wall, or the porous walls permit of the foul air being sucked through the walls into the warm rooms.

In London they are mostly constructed underneath the area steps, and their exhalations breathed by servants, tradesmen, and passers by; but frequently it will be found that one of the area vaults has been appropriated, and it needs no argument to show how such large receptacles must affect the sweetness of the basement. I have more than fifty times also found the dust-bin inside a vault which is enclosed in the house, and thus virtually poisoning its atmosphere. Very often, too, just above the dust-bin will be found a cistern, with a badly-fitting cover, and supplying some of the sinks in the basement.

The contents of all dust-bins, at least in London, resolve themselves into four products:—1. The 'ash,' or that compound of fine ash, boot brushings, house dust, &c., which is for the most part moulded into bricks. 2. The ashes or cinders and fine coal which will not pass through the sieve with the foregoing, and which is called 'breeze' and used as fuel where-with to bake the bricks. 3. 'Hard core,' such as broken pottery and other hard refuse which is not worth selling, and is chiefly used for road-making. And lastly, 'soft core,' which means all kinds of animal and vegetable refuse, of course the most difficult material to deal with, necessitating, as in the case of Lambeth heaps, sprinkling with carbolic acid powder before it is bargained away for agricultural purposes.

the most complete treatise dealing with the collection and removal of refuse from houses, as sanctioned by every local authority by the Public Health Act, 1875, is that of Mr. Percy Boulnois, which will be found under the head of 'Sanitary Engineering,' in his work published in 1883, entitled 'Municipal and Sanitary Engineers' Handbook,' which enters fully into the law of dust removal, and rather to make a few remarks concerning the practice of dust removal as it is carried on in London. Dust is either collected by scavenging carts,

By far the greater number of the metropolitan vestries, viz.:

The Strand	Poplar
Westminster	Hampstead
St. Giles	St. Pancras
Holborn	St. Saviour's, Southwark
Rotherhithe	Lambeth
Shoreditch	Camberwell
Hackney	Wandsworth
Bethnal Green	St. Marylebone
Whitechapel	Chelsea
St. George in the East	Limehouse

contract with different parties to call round at every street in the district from twice a week to once a fortnight, in most cases, they paying the contractor to cart the dust away. The contractor has in the majority of cases, a wharf on the river or canal, as the case may be, where he either sifts and sorts the refuse and disposes of it piecemeal—the 'ash' and 'breeze' to brickmakers, the 'hard core' to contractors for road foundations, and the 'soft core' to market gardeners and farmers for manure, or he shoots the refuse direct into barges, without sifting, and disposes of it as it is to brickmakers. If he finds no ready market for the dust, &c., he either lets it accumulate or takes it down the Thames, presumably beyond Lee Reach, and shoots it into the water.

In the case of some of the outlying districts, such as Hampstead, the contractors simply cart the refuse and dust in bulk to brickfields in the neighbourhood. Many of the vestries contracting as above are thinking of adopting better methods of disposal and working the system themselves, thus saving expense. The Poplar Vestry have just instituted pails in place of dust-bins, and are negotiating for a piece of land, where they propose erecting a furnace and trying burning the greater part of the refuse.

The system adopted by St. Olave's, Hammer-smith, St. George the Martyr, and Bermondsey is somewhat similar to the above; they have a wharf in their respective districts, where they shoot the dust, sift and sort it, and then contract with a man to take it away.

Islington, Plumstead, Mile End, Woolwich, Lewisham, Clerkenwell, Greenwich, Kensington, St. Mary's (Newington), Paddington, St. Luke's (City Road), and the City Commissioners dispose of all refuse themselves. Of these, Clerkenwell, St. Luke's (Paddington), and Plumstead have a wharf where they sort, and whence they barge away to sell for brick-making, road-making, and manure.

Islington, Mile End, and St. Mary's (Newington) have a dépôt, where they screen into trucks and send off to the country by rail.

Lewisham, Greenwich, and Kensington shoot at various places, without sorting, at any place in the district; in fact, where they can find a market, the places being mostly brickfields.

Woolwich shoots at Charlton, where there is a place wants filling up.

The City Commissioners burn their refuse. Of the above, special mention should be made of St. Mary's (Newington), Paddington, and the City Commissioners.

St. Mary's (Newington) have a large dépôt in their district of Walworth, on the London, Chatham and Dover Railway, and one in the country at Longfield. Their carts call round at each street once a week and take all dust, refuse, and slops to their dépôt in Walworth. Here the dust and refuse are sifted and

sorted in the way common among the contractors by women. The ashes and breeze are sold to brick-makers, the hard core for road foundations, and the soft core and slops (after being treated as explained hereafter) for manure.

The manure or 'mixture,' as they term it, is made in the following way:—A large bed is made about eight inches deep, of old straw, bought by the vestry from the various stables in the district. On this foundation the soft core, consisting of paper, rags, peel, &c., is spread, then another layer of old straw, which is heaped up at the edges so as to form a basin or tank about four feet deep. In this basin the slops obtained in wet weather are emptied, and dry dust is sprinkled on the top of all. The bed thus formed is then allowed to stand for a week or so, at the end of which time all the superfluous water has drained away through the straw, and the 'soft core' has fermented and rotted and become thoroughly decomposed. The bed is then mixed up and sent away in trucks to the country, where there is a very ready sale for it among the farmers for manure. As many as thirty trucks a day are sent away from here sometimes. They have six of these beds, which they work alternately, and there is very little perceptible odour arising from them.

The country dépôt at Longfield is used for storing the ashes, &c., when there is not a ready market for them. The system appears to work very well.

The Paddington system is chiefly remarkable for their method of sifting and sorting by machinery, thus to a great extent obviating the necessity of employing the manual labour of women. The dust, &c., brought in by their carts is shot into a large screen, which separates the larger materials such as flower pots, bottles, and culinary utensils. The smaller material is carried up by buckets fixed on an endless chain, and is emptied into two sieves placed at an angle to each other like the roof of a shed. The paper, bones, &c., collecting on these is raked off by women and sorted, and the dust and ashes falling through is brought up by another system of buckets on an endless chain, and conveyed along a wooden trough into the barge, where it is taken away and sold to brickmakers. The soft core sorted out is sold as manure or burned, and the hard core is used for road foundations as usual, the flower pots, &c., being taken out, of course, and sold separately. The slops are emptied into a large tank built of wooden planks, the planks being placed some two or three inches apart, and the crevices thus formed filled with straw. Through this straw the water drains, and runs away into the sewers. The resulting dry mud is barged away and makes a good mould.

The yard is kept in very good order and is quite extensive, all the vestry carts being made here, and the horses being stabled and shod here.

The City Commissioners of Sewers burn their refuse, and the system is said to give every expected satisfaction. The other vestries who make use of a furnace for burning some of their soft core—the Newington and St. Olave's—are of opinion that the refuse burns very slowly and is very troublesome.

The system of destruction of all kinds of house refuse by burning it in suitable furnaces was reported upon by Dr. W. Sedgwick Saunders in 1851, and it may be taken as forming the most complete essay upon the subject. In this process—which has been largely adopted in Leeds, Bradford, Warring-

n, Manchester, &c., &c., and in continental countries—an apparatus which is termed a 'destructor' destroys by fire everything combustible in household refuse; and the second apparatus, which is called the 'carboniser,' deals with the vegetable matter and converts it into charcoal. At Leeds large masses of refuse, house dust, market and aged street sweepings, midden night-soil, are delivered on the top of the 'destructor,' and as the material perishes from below it sinks down the surface holes; and at the front, pots, pans, glass, rockery, clinkers, and all coarser materials are extruded. The large quantities of iron utensils fall to the front, and are raked out and allowed to cool, and afterwards sold. When the clinkers, molten metal, and glass (all of which are fused together) has been drawn from the 'destructor,' the clinkers which result from the process of burning the refuse are in some places ground into powder, and when mixed with lime and water it forms a cement which is much sought after. Hard bricks are also made from the same material.

I have nowhere in this paper referred or intended any reference to the treatment of condemned meat and the best method of dealing with that, but have confined myself simply to the disposal of the dust from ordinary dust-bins. I may mention, however, incidentally that there can be no doubt that 'the carcass-crusher, or devil,' at work near Warrington, &c., which breaks up the body, and which is afterwards treated by the rotary fat rendering machine of Mr. Firman, is the completest and most satisfactory method of dealing with that.

Mr. Healey, of Brig House, near York, has lately brought out an improved furnace for converting town and other refuse into clinkers, which appears to be very simple. It would have the apparent advantage over some other methods, that very bulky refuse could be destroyed in it, such as bedding, mattresses, and the like.

I think most people will agree in thinking that any system of taking the refuse of towns or cities by barges out to the sea and emptying them there, must give a very poor notion of how far more satisfactorily and economically this material can be disposed of by separation, appropriation, or destruction. At New York, and I believe in Liverpool, a great deal of refuse has been got rid of by sea immersion, but would appear that it was simply for want of space and convenience to utilise it that this crude system of disposal was resorted to.

After a due consideration of the foregoing statements, I think it will be taken for granted that the burning of the refuse is the most satisfactory system extant. There seems to be a very general feeling in favour of this mode of disposal, provided it can be effected easily, and numbers of the vestries are watching with interest the results obtained by the City Commissioners and the system adopted by St. Mary's (Newington).

MESSES. ARCHIBALD SMITH & STEVENS, of 48 Leicester square, and Queen's Road, Battersea, have been awarded silver medal at the London International Exhibition, Crystal Palace, 1884, for their exhibit of Stevens & Major's Patent Silent closing Door Spring.

THE Gateshead School Board have decided to introduce into some of the Board schools the system of providing penny dinners for the children. The plan has already been successfully adopted in the town by the vicar, the Rev. W. Moore Ede, manager of one of the schools.

SEWAGE DISPOSAL.*

By Professor HENRY ROBINSON, M.Inst.C.E.,
F.G.S., F.M.S.

THE outcome of several public inquiries which have taken place during the last year or two, and of much valuable data derivable from other sources, establish, we think, a well-marked advance with reference to sewage disposal; and it may be of use, as well as of interest, if we lay before this Congress the conclusions which, we conceive, are deducible therefrom. We propose to deal with the subject under the following heads: 1. Sewage disposal on land. 2. Sewage disposal by chemical treatment. 3. Sewage disposal by discharge into a tidal river, or into the sea, without treatment.

I. SEWAGE DISPOSAL ON LAND.

The object of dealing with sewage on land may be taken as twofold, namely, to purify it (which is the sanitary object), and to utilise its manurial products (which is the agricultural object). Where want of skill, or where prejudice has existed, these two have not been properly separated, and the results have been in many cases unfavourable to sewage disposal on land from either of the before-mentioned points of view.

It has been regarded as an axiom that clay land cannot be employed to clarify sewage. This is true when it is proposed to pour the sewage on it as if the land were porous. Very recent experience, however, has led to clay land being converted from an impervious to a pervious condition, by which it has been successfully utilised. This is effected by digging out the clay to a depth of about 6 feet, burning it into ballast and replacing it in layers, interposed with an occasional layer of open alluvial soil, the whole area being well drained with a free outlet for the effluent. We have successfully carried this plan out, and with this result, that whereas it was not possible previously to clarify the sewage of 100 people to an acre of clay land, the prepared filtration area has been able to continuously clarify the sewage of about 1,500 people to the acre. The cost of converting clay land into this form of filter may be taken as varying from 750*l.* per acre to 1,000*l.* per acre according to local circumstances. One area which we have just completed has cost 1,000*l.* per acre. Before sewage is passed on to these filters (or on to land) it should be strained so as to remove the larger particles. The best arrangement for this purpose is to pass the sewage upwards through a straining medium (not downwards), and to run the solids from the bottom of the straining tank on to a low-lying piece of land for digging in as they are run out.

Where such a filtration area is made to form part of a sewage farm it acts as a safety-valve, and enables the land and crops to have a rest when they do not require further irrigation; at the same time the process of purification is not interrupted.

If open porous land is available for sewage purification, and if it can be drained 6 feet deep to a good free subsoil, so that the effluent can get readily away, we find that the sewage of from 600 or 700 people can be dealt with on each acre per annum with both good agricultural and sanitary results.

In my Address as President of the Engineering

* Read at the Congress of the Sanitary Institute of Great Britain, at Dublin, Oct. 2, 1884.

and Architectural Section of the Congress of this Institute at Newcastle-upon-Tyne, in 1882, I directed attention to the important investigation which had been conducted by Mr. R. Warrington, of Rothamsted, the result of which was to show the action which goes on in the soil when sewage is passed through it. Further information, which the same observer has published since that date, is of equal value, and deserves to be read by all who have to advise in regard to sewage disposal on land. The process of 'nitrification' (as it is termed), which he has so fully investigated, consists in the conversion into nitrates (which serves to nourish plant life) of the organic matter in sewage. This takes place by the action of a living ferment of the bacteria family, which is created by and feeds on the impurities in sewage, and these organisms both consume the impurities and convert them into nitrates.

The action of living agents thus brings about the oxidation of the organic matter in sewage, just as worms, larvæ, fungi, and insects, feed on the vegetable matter in the soil, increasing the amount of nitrogenous material in it.

Experience during the past year or two has proved the feasibility of preserving green crops in a succulent state by compressing them in silos, so that they can be utilised for cattle fodder in the winter. This system deserves notice in connection with sewage farming, as I am of opinion that it will prove a valuable means of getting over the well-known practical difficulty which is experienced of finding a market for the large amount of green crop which is produced by sewage irrigation.

2.—SEWAGE DISPOSAL BY CHEMICAL TREATMENT.

In the last edition of my book on 'Sewage Disposal,' in speaking of precipitation, I said that 'the purification of sewage by chemicals has been the subject of misapprehension, owing to the extravagant advantages which have been claimed for the system by its advocates.' This is even more true now than it was two years ago, inasmuch as in the recent scheme for dealing with the sewage of the Thames Valley chemical treatment *per se* was relied on to produce from the sewage of a future population of 350,000 an effluent at all times fit to be discharged at one point into the River Thames above London, but the Parliamentary Committee rejected it. One part of the report of this Committee deserves attention, when speaking of sewage treatment by chemicals. It is as follows:—'Your Committee believe that in these cases the process of filtering the chemically purified effluent through earth ought, if possible, to be adopted, which was not provided for in the scheme under their consideration.' This opinion is exactly in accordance with our experience, and is that which I have held throughout. It is at the root of the whole matter, because efforts are made by those interested in chemical processes to attain as high a standard of purity as possible with the attendant heavy expense of chemicals. Experience shows that it is impossible at all times and seasons to be sure of a constant and uniformly high standard of purity, and that chemical works should be supplemented by a filtration area, however small. The addition of this, however, enables a lower standard of effluent from the precipitation tanks to be admissible, and this can be attained with very simple and inexpensive chemicals.

In the course of our practice I have had to ad-

vise as to the majority of the processes, and to design the works for their being carried into operation. I have found that the cost of such works complete varies from '091 to '166 of a £ per head of the population, and that the average cost of the works at several towns which we have been connected with is '123 of a £ per head. This figure may be conveniently followed by that of the cost of treatment, which I find varies from '036 to '110 of a £ per head per annum, and an average of several places gives '06 of a £ per head per annum. The above figures apply only to places where the very highest standard was sought to be attained, but my more recent experience leads me to modify the arrangement of the works and the cost of treatment, so as to rely on filtration of the effluent as an important factor. I estimate that under these conditions the cost of the works complete would be about '075 of a £ per head, and the cost of treatment '04 of a £ per head per annum.

The disposal of the sludge has always been a difficulty in these works, but this is now overcome in two ways: either by digging it into the ground, as is done at Birmingham now, or by pressing it into cakes in filter presses. It is found at Birmingham that one ton of sludge with 90 per cent. of moisture is produced from 1,000 people. There the lime process is used. I have found that about one ton to 2,000 people is produced where a salt of alumina or iron is used with the lime. At Birmingham the sludge is dug into the land adjoining the works, and it is found that one square yard of land will take one ton of sludge with 90 per cent. of moisture once in three years, which results in three yards of land being required to be provided for each ton of sludge. This system of digging in sludge is successfully carried out as regards freedom from nuisance. Where land is not available to dig in the sludge it is necessary to make it portable for removal and disposal away from where it is produced. This is best effected by filter presses. Appliances are made for this purpose, by which the sludge is pressed to a consistency of about 50 per cent. of moisture. The cost of effecting this is about '007 of a £ per head per annum. It is found in practice that where the sludge is produced by straining the solids from sewage before passing it on to land for purification, it requires a little lime to enable the press to work well. About two barrow-loads of lime for each ton of pressed sludge suffices.

It has been thought that the cost of precipitation would be covered, and even a profit gained, by the sale of the sludge. This hope, however, is not nearer realisation now than it was in the time, now gone past, when chemical processes were relied on to turn sewage from a profitless into a profitable commodity. There is, consequently, less justification now than there was at that time for adopting a precipitation system for sewage disposal. It is entirely a question of carefully considering the engineering and financial points involved, regardless of the sanguine representations of interested or enthusiastic advocates of any particular system.

As the estimated manurial value of the sludge which is precipitated from sewage by the addition of chemicals does not seem to be capable of realisation, I think that probably the reason may be found in the fact that the chemicals arrest that process of decomposition which is essential to the conversion of the organic matters into nitrates for vegetation to utilise. This explanation will be under-

stood in the light of what we have already described in regard to 'nitrification.' If this view is correct, it would follow that the more completely and permanently the sludge is deodorised by the chemicals the less capable is it of passing through the necessary stages of decomposition by which its manurial value can be realised.

As mistakes are constantly being made in regard to the weights of sludge with varying degrees of moisture, the following table may be useful :

100 tons of sludge with 90 % of moisture = 50 tons with 80 %			
100	"	"	33'3 70 "
100	"	"	25 60 "
100	"	"	21 50 "
100	"	"	16'6 40 "
100	"	"	14'3 30 "
100	"	"	12'5 20 "
100	"	"	11'76 15 "

3.—SEWAGE DISPOSAL BY DISCHARGE INTO RIVER OR SEA.

I will next deal with the conditions which should be fulfilled where it is sought to utilise a river or the sea into which to cast the sewage of a town. If it can be ascertained beyond question that at the proposed point of discharge the currents at all times will carry the sewage right away, and will not at the same time produce mischief at a distance (which is often omitted from the consideration), then that arrangement may be accepted as a good one. This, however, seldom occurs.

A river has been looked upon by manufacturers and local authorities as the natural carrier of their refuse from their district. This view has been persevered in, in spite of the River Pollution Prevention Act of 1876, which is practically a dead letter. The public, however, who use a river either for pleasure purposes or for obtaining their water supply, have of late years grown more and more united in their efforts to stop this abuse, and there is no doubt that these efforts will eventually succeed. In a paper which I read last year at the Congress at Glasgow, I pointed out the steps that were necessary to be taken to render this Act operative, and I refer my readers to that paper if they wish to follow the matter further.

The effect of discharging sewage matter into a river has been the subject of much controversy amongst chemists. Some allege most positively that the injurious properties in the sewage are indestructible. This has led to alarmists demanding that under no circumstances ought sewage to pass untreated into a river. I have given considerable attention to this vexed question, as it requires to be grasped by any engineer who has to advise on the selection of sewer outfalls, and it appears to me that the balance of evidence is against the alarmists. Every river has a certain power of oxidising impurities, in proportion to the extent of oxidation of the river itself. Besides this, there are the powerful purifying influences exercised by the plants and animalculæ which exist in rivers.

It has been ascertained that entomostraca consume dead animal matter, and where this is wanting they do not live, but where it is in abundance they thrive. It follows, then, that these minute animals exercise an important function in absorbing sewage impurities. They multiply prodigiously in these impurities, and are both created by them and fed upon them, converting foul and dangerous matters into harmless ones, in a similar way to that which we have referred to as nitrification when speaking of the action of bacteria in the soil. Considering that these

organisms arise from and are fed on concentrated filth, it is obvious that they cannot live when the conditions favourable to their existence disappear. This would be the case when the sewage is discharged into a large volume of water with a different temperature to that which suits them, and with powerful oxidising influences at work. These conditions, added to the difficulty they must experience to find their natural food—namely, concentrated sewage—where the sewage matter becomes so greatly diluted, accounts for the fact that in a short run of a good river sewage impurities largely disappear. The action of weeds and plants also aids purification to a very large extent. Minute plants, such as coniferoid algæ and the like, also assist in oxygenating the river, as when exposed to light they decompose carbonic acid, and liberate oxygen.

The practical question which has to be answered in every case where sewage is proposed to be discharged into a river requires to be approached from two points. The first is whether a nuisance will be caused at the spot to which objection would be taken. If this is likely to be the case then the fact that the sewage will get purified in a short run of the river does not meet the objection. The second point requires a careful consideration of the condition of the river, both from an engineering as well as from a chemical and biological point of view. Decisions on these matters have too often been arrived at in a rough and ready way. They require skilful treatment, as the interests—both commercial and hygienic—which are affected are too great to permit of them being dealt with by any who are not well informed and careful.

The general conclusions which I deduce from my observations are as follows :

1. That chemical precipitation is not so necessary now as it was considered to be a few years ago in cases where land for irrigation is not procurable.
2. That the efforts to profitably remove the manurial elements from sewage by chemicals not having been successful, the system should be adopted *per se* only where a filtration area cannot be obtained.
3. That the success which has attended the construction of filtration areas where the land is clayey, and the successful results which have been obtained from a combined straining of sewage and of subsequent filtration through small areas of artificial filters, point to the adoption of one or other of these systems in many cases where chemical treatment would previously have been advised.
4. That the injurious effects of passing untreated sewage into a river depend upon not merely the relative volumes of the sewage and the river, but chiefly upon the power of the river to oxidise the sewage, which power is in proportion to the extent of oxidation of the river itself.

MESSRS. ROBERT BOYLE & SON, Ventilating, Sanitary, and Consulting Engineers, 64 Holborn Viaduct and Glasgow, have been awarded at the Art and Sanitary Exhibition, Eastbourne, the first prize medal (silver) for their systems of ventilation, sanitation, and heating, and their patent self-acting air-pump ventilator ; being the only award given for ventilating and sanitary appliances.

THE Health Committee of the Liverpool Corporation recommend the appropriation of twenty-five acres of Wavertree Park as a site for a hospital for infectious diseases. They recommend the erection of a series of buildings with a wide belt of land and trees to secure isolation.

THE SANITARY RECORD.

OCTOBER 15, 1884.

The Editor will be glad to receive, with a view to publication, announcements of meetings, reports of proceedings, and abstracts or originals of papers read before the members of any sanitary or kindred association.

MUNICIPAL FINANCE.

THE minds of ratepayers in some of our large and more go-ahead cities are beginning to be stirred at the generosity with which their finance committees are spending money on public improvements by means of borrowed money, which the next generation will have to repay. Indeed, the whole subject of Municipal Finance has been receiving considerable attention of late; what with the defalcations of one borough treasurer after another, the granting of annuities on what have eventually proved to be ruinously improvident terms, and the ambition of corporations to administer everything themselves—from the supply of water to immense areas to the making of patent manure, from the establishment of art schools to the running of a hotel—Nottingham is an excellent example of the spread-eagleism now rampant in some of our large towns, and its recent prominent position in connection with the extension of university teaching and in other ways invests its balance-sheet with a more than local interest. The *Nottingham Journal* has been indulging in reflections as to the expenditure of the present and the past, and prints some very interesting figures which serve to show the developments of municipalities during the present century. The total expenditure out of the Nottingham Town Rate in 1803 was but 2,983*l.*, and in 1807 it was 2,901*l.* In the year ending March 25, 1884, the amount raised by the district rate for town purposes was 142,190*l.* besides 20,300*l.* taken from the gas and water profits, 9,970*l.* received from rents of the Chamber Estate, and 9,623*l.* rents of the Bridge Estate. At the beginning of the present century when the town expenditure was such a small affair, sewage farms, university buildings, school boards, castle museums, recreation grounds, the police system, gas lighting, and sanitary arrangements, such as now exist, were unknown. Last year the cost of the police force alone was 20,114*l.*, including 1,375*l.* for clothing and accoutrements, this latter item being about as much as was paid to the constables altogether eighty years ago. No charge appears in the accounts of 1803 for lighting the town, whereas last year the cost of public lighting came to 10,488*l.* Nottingham, at the beginning of the present century had no occasion for public recreation grounds, for the town was then small, and surrounded by Lammas land, over which the public had the right of roaming at will during many months in the year. Now all is changed, and its recreation grounds cost pretty nearly 4,000*l.* a year in maintenance alone, besides 2,400*l.* which is spent on the Castle Grounds and Museum in excess of the receipts. In 1807 the town authorities did not concern themselves with sanitary matters, but last year the Health Committee

took 28,343*l.* for their operations; the Works and Ways Committee nearly 35,000*l.*; and the School Board for education purposes about 19,000*l.* In 1807 the ratepayers of Nottingham were in blissful ignorance of the meaning of a Town Debt, and beyond an occasional small overdraft at the bankers had few liabilities. Now the town authorities have just placed a second loan of a million sterling, and the amount, which figures in the accounts of the last financial year for loans and interest was 36,616*l.* The town now spends thousands of pounds on new drainage schemes, managing the Sewage Farm, and other matters too numerous to mention. In 1807 the town expenditure was 2,901*l.*, whereas the estimate for the current year is 212,763*l.* In the first-named year the population of Nottingham was a little over 28,000, and the cost of municipal government came to about 2*s.* a head; now the population is estimated at 205,000, and the cost of municipal government exceeds 1*l.* a head, besides a debt amounting to about 9*l.* 14*s.* for each inhabitant. It is evident, says our contemporary, that if the inhabitants of Nottingham to-day enjoy greater advantages than their ancestors they are called upon to pay more than double what their ancestors used to do.

VENTILATION OF PUBLIC BUILDINGS.—Messrs. Robert Boyle & Sons, 64 Holborn Viaduct and Glasgow, have just applied their Patent Self-Acting Air Pump Ventilators, and system of ventilation, to the Inland Revenue Department, Somerset House; Gresham Hall, Brixton; University College, Bangor, North Wales; Council Room, Barnsley; Masonic Club, Landport; Alexandra Club House, Southend; Free Library, Northwich; New Offices, Edmonton Local Board of Health; York Institute, York; Carr & Company's New Stables, Carlisle; New Factory for the Ekman Pulp and Paper Company, Northfleet; 'Lillehurst,' 'Simoonstown Hawes,' 'Stratland Park, and Muncaster Castle, residences of the Duke of Sutherland, Lord Wharfedale, Sir G. Brooke Middleton, Bart., and Lord Muncaster.

INFANT LABOUR IN FRANCE.—In his report to the President of the French Republic upon the results of the inspection of manufactories in order to see that the law as to infant labour is carried out, M. Corbon, President of the Committee of Inspection, gives some interesting information as to the working of this measure, which was only passed in 1874. The number of establishments inspected last year was 46,314, and though this is nothing like all the manufactories and workshops in which children are employed, there has been a steady increase since the law first came into force. The establishments inspected are of every kind, but the law makes an exception in favour of charitable institutions and establishments belonging to the State, exceptions of which the president of the committee questions the expediency. The number of children in the 46,314 establishments inspected last year was 213,001, and it is pointed out that there is a marked falling off in the total of children employed in these establishments, this being attributed in part to the fact of their parents finding more lucrative employment for them, in part to the operation of the law of 1882 with regard to compulsory education. The law of 1874 fixed twelve as the minimum age at which children were to be employed in manufactories and workshops; but an exception was made in favour of one or two light kinds of work, when ten was the minimum age. But while only 7,780 children were so employed in 1875, the total has gradually dropped, and was only 4,254 last year. The inspectors report that the rules as to Sunday and night labour are generally well observed, but that there is great delay in informing them of the accidents which may occur, and of which there were 175 last year.

NOTES OF THE MONTH.

THE HASTINGS HYDROPATHIC ESTABLISHMENT AND SPA.

HASTINGS, one of the most charming and favourite resorts on the south coast, has now been provided with a first rate hydropathic establishment. This has been done by a company under the Limited Liability Acts, with a board of five directors, one of whom, Mr. Liddiard, the chairman, has visited and carefully inspected nearly every similar institution of any note, the result being that every improvement has been introduced, and everything done to make the Hastings establishment one of the most perfect in the kingdom. It was formerly the residence of Mr. Frederick North, M.P. for the borough, and has been taken on lease for forty years with the option of purchasing the freehold. The mansion stands in five acres of well wooded grounds, in which there is a valuable mineral spring, similar to the far-famed Tunbridge Wells spring, but containing a somewhat smaller quantity of iron, in a most beautiful situation on a slope in the Bourne Valley; well sheltered from north and east winds by the surrounding hills, with extensive and uninterrupted views, and within a few minutes' walk of the parades and principal part of the town. The baths are as complete as money, capital, and skill can make them, the water supply is abundant and good, and the sanitary arrangements are perfect. The public rooms are large, commodious, and fitted with every convenience, in addition to which there are several elegantly furnished private sitting-rooms with bedrooms *en suite*. The Hastings Hydropathic Establishment and Spa is not intended for confirmed invalids, and patients suffering from mental or infectious diseases, epilepsy, or dipsomania are not received upon any terms.

PENNY DINNERS FOR BOARD SCHOOL CHILDREN.

IN reference to this question, Mr. Jonathan Taylor, member of the Sheffield School Board, communicates his experience in providing penny dinners to the *Schoolmaster* of Sept. 13. He writes:—'In the month of June last the Sheffield School Board set apart two rooms in one of its schools, situate in the poorest district of the town, one of which has been fitted up as a kitchen, and the other for a dining-room, the expenses incidental to the same being provided by a committee who, apart from the board, undertake the entire management, finance and otherwise. The dinners are open to every child attending the schools, no questions being asked as to the position of parents, and consequently no invidious distinctions are made. A few minutes after twelve o'clock a teacher from each department marches the pupils from his or her school into the dining-room, where the cook has already got the tables covered with nice clean white cloths, bright spoons and forks, with an abundant supply of pure water to drink. The dinner consists of two courses, and is varied from day to day, but the following will fairly indicate both the quantity and quality and cost of the provision made:—

'DINNER FOR 200 CHILDREN.—SOUP.—7 lbs. 2 ozs. of Australian beef, at 5½d., 3s. 2d.; 4 lbs. of flour, at 1½d., 5d.; 36 lbs. of potatoes, at 5d. per stone of

14 lbs., 1s. 1d., 2 lbs. 6 ozs. of rice, at 1½d., 3½d.; 1½ lbs. of onions, at 1½d., 2d.; pepper and salt, 2d.; total, 5s. 3½d.

'JAM PUDDING.—28½ lbs. of flour, at 1s. 5d. per stone of 14 lbs., 2s. 11d.; 2 lbs. 6 ozs. of suet, at 7½d., 1s. 6d.; 8 lbs. 5 ozs. of jam, at 2½d., 1s. 9d.; baking powder, 2d.; 1 lb. of sugar for sauce, 2d.; salt, ½d.; total, 6s. 6½d.

'It will be seen from the above that for a total cost of 11s. 9½d. a good, wholesome, and substantial dinner can be provided for 200 children, which is a little less than ½d. per child, and from an experience now extending over some weeks, I can assure your readers that the provision is ample. Of course to this must be added cost of fuel and cooking, which will vary a little in each locality.'

These practical details of cost will be useful to committees desirous of extending the system of supplying penny dinners now under trial. (See SANITARY RECORD for Sept. 15, p. 122.)

A PREMIUM ON INFANTICIDE.

A RECENT letter to a daily contemporary draws the attention of the public to an evil, the existence of which is only too well known to those who have any acquaintance with the lives of the poor. The writer, signing himself 'M.R.C.S.', cites a case coming under his own notice, and which is doubtless typical of many in the experience of other practitioners. An infant (he says) was brought to him with a slight ailment, from which it would have soon recovered had it been properly cared for. However, after two or three days it died, and inquiries were instituted, showing that it had fallen a victim to the pernicious system of infant life insurance which prevails in most large towns. As soon as a child is born its parents obtain a policy on its life, and from a half-penny to twopence (according to the sum insured) is paid weekly to the collector of the insurance office, who is grimly known on his rounds as 'the dead man.' The policy is void if the child dies within three months, but when once this minimum age is reached the sum insured is paid by the office on the production of a certificate of the child's death. In the case referred to about 1s. 6d. in weekly pennies was the amount paid in, and the parents received 1½ 5s., a sum much beyond the cost of burying an infant among the poor. The system unquestionably puts a premium on infanticide. It is not only easy to get an infant insured, even though it be weak or sick, for one society's 'dead man' competes with another society's 'dead man,' and both are paid according to the amount of business done; but little or no inquiry is made after death for fear the society should get a 'bad name.' Then comes the temptation to the vicious or the very indigent—that the child's death represents an immediate money gain. The temptation is ever present, and leads to carelessness or actual neglect, or to the use of one of the many poisons which can be obtained with such easy facility under the names of cordials, or carminatives, or soothing syrups. Such preparations are patented, and can be sold by any huckster who chooses to pay a few shillings for his licence; and with them is sold a salve for the poisoner's conscience, for are they not all recklessly labelled as 'perfectly harmless'? And unless the neglect is very gross, or the overdose of carminative very large, the medical man is powerless. There is no positive proof. Mere suspicions will not warrant

further inquiry; and if they should, the coroner commonly takes a merciful view of the matter.

The statements of 'M.R.C.S.' have evoked a letter from 'A General Practitioner,' who endorses the view that the wholesale insurance of infants is one of the causes of excessive infant mortality in this country. He says that policies are issued on lives of children concerning whose state of health at the time no inquiries whatever are made. Though there is thus no care in the selection of lives, the companies thrive, as a considerable percentage of the policies are forfeited on account of the weekly payments not being kept up, the amounts paid being forfeited also. The whole system seems utterly bad.

PIPE SEWERS IN COLUMBIA.

IN every part of the city of Columbia, where pipe sewers have been laid for a number of years, portions of them are found more or less obstructed by the roots of trees, in some instances quite filled with them. The pipes were laid without foundation of any kind upon firm ground. In process of time the leakage from the joints softened the ground beneath them, and the weight of the covering earth in the trench forced the pipe down irregularly into the softened ground. A small amount of settlement sufficed to open the joints, and the fine roots of trees found ready access to the interior. Here they grew and multiplied rapidly, arresting and collecting sand and clay brought in by storms, until the pipe was completely choked up, and a section of it looked like a section of a large flower-pot in which a plant has been growing for a long time.

DANGEROUS STAIRCASES.

AN inquest was recently held as to the death of a man from injuries sustained through falling down stairs at Corporation Buildings in Farringdon Road. It was stated that he had had a little drink but was not drunk, and the accident was entirely owing to the dangerous state of the staircase. Upon examination it will be found that this was unhappily the case, as many serious defects are in existence, and many falls are thereby occasioned from time to time. These buildings are 'model dwellings,' belonging to the Corporation of the City of London, and it is very discreditable that such a state of things should be allowed to continue, more particularly when (according to tenants' statements) complaints have been frequent. The staircase is spiral, and the steps therefore are narrower at one end than at the other; this form though frequently used is very objectionable and dangerous, especially when serving a large number of tenements. The width of the tread at the widest part is 14 inches and at the narrowest about 6 inches, not 3 inches as stated at the inquest. To make matters worse, however, the surface is very slippery, the material of which the steps are made being a concrete of cement and 'breeze' which is generally used for work of this class, on account of its cheapness and durability. The concrete is finished with a very fine surface and becomes absolutely polished by wear. The edge of the top step is rounded off in a particularly dangerous method by having an iron nosing, and as far as can be ascertained, it was from this particular step that the deceased fell. There is no handrail on either side to help the victims (we use the term advisedly), and those who have to pass on the inner side run

constant risks without a chance of saving themselves. There is plenty of light to the during the day; and although (as is usual in places) gas is provided, it is only lighted during the evenings of the winter months—viz., from Christmas to Lady-Day. The fact that the accident happened when it was light only serves to the evils adverted to, and to warrant the verdict by the jury that they considered that the Corporation had shown great negligence in the matter, recommended that a handrail should be put up. As regards the slippery state of the steps, or nosing of different material can be substituted. This should have a rough surface to form a foothold, and when worn away or defaced it should easily be replaced. Such things are done in other places, why not here? Human life is cheap, but the Corporation need not be the means of allowing it to be wasted.

Another inquest was held respecting the death of a child—a girl seven years of age, residing at the Minton Road Block of the Palatinate, 1, Minton Road, who was killed through falling down a staircase. The evidence showed that the child had been in the habit of sliding down the stairs, and on this occasion she had fallen over the side, so fracturing her skull. The coroner observed that he had had occasion to hold inquiries on the death of children who had met with their death in the same buildings in a similar manner, and that on each occasion recommended that iron spikes should be fixed on the handrails to prevent sliding down them. He was sorry to see that the Corporation's commendation had not been carried out. The jury agreed with the coroner's observations, and expressed an opinion that the staircase in question were nothing short of traps, the banisters at some points being broken over two feet in height. Although in this case the death of the child was in a measure owing to her own doing, there is no excuse for the Corporation allowing such a result to be possible. Properly fixed spikes sufficient to prevent sliding, yet not so injuriously to the hand, could with a little more care be fixed; and it is to be hoped that the coroner's representations will not again be overlooked, and it must be remembered that the Corporation's negligence on the part of the proprietors may be of proportions of greater magnitude than they are, and from the consequences of which they should be always exempt.

Still another case is reported from University College Hospital, that of a woman, 60 years of age, who lived at 88 Cleveland Street, Middlesex. When going out to buy some articles for the house, going downstairs, which had neither handrail nor rope, she fell, sustaining injuries which necessitated her removal to the hospital, where she died. The house surgeon stated that when admitted she had a superficial wound on the back of her broken wrist. The *post mortem* examination showed a fracture of the skull and internal hæmorrhage thereon. The jury returned a verdict of death, adding a rider that they strongly advised the landlord to remedy the defect in the staircase to prevent the repetition of such a fatal case, which unhappily are only too common to a gross disregard of the ordinary interests of tenants, and, although in the lower class tenements such fixtures as wooden handrails are commonly destroyed and used as firewood by the old

no excuse for the proprietors and landlords to evade moral responsibility, as rope or iron can easily be made, and comparative of life and limb thus obtained.

THE DANGERS OF THE STREETS.

Many well-known dangers to pedestrians on streets may be added the defective or irate of the kerb to the pavement. We are so accustomed to good and level paving that occasional inequality of the surface is often met with at any rate disagreeable results, and expected height for a footstep is quickly . . . A boy four years of age ran across the way at Alscot Road, and attempted to step—or for him to have been almost to climb—upon a curb, which was nine inches high, and in so doing he stumbled and fell in the gutter; and a van along at the time caught the poor little notwithstanding the driver's efforts to avoid it, and he became crushed between the rear wheel of the van and the kerbstone. He was taken to a neighbouring surgery, but sank rapidly, and died two hours after from the injuries received. The jury returned a verdict of 'Accidental death,' finding the driver of the horses and van from blame. The fault, then, may be partly attributed to the unusual height of the kerb, which usually is only six to six inches deep, and should rarely be more. It is of course deepest at the crossings—that is, if the road be level, as it must be made for running off the water. The steps vary from five to seven inches in height, and an extra inch or two is the cause of inconvenience; and in the dusk or dark the danger may be attended with serious consequences even to adults. In a position like this it is doubly dangerous, and the attention of the vestry may be called to it with advantage.

MACHINERY ACCIDENTS.

A fatal accident through machinery is recorded from Rotherhithe. An engineer and thirty-seven years of age, was discovered in the cockpit of the engine in a fearfully mutilated and quite dead. The chief engineer stated that there was a guard protection at one end of the machinery but not at the other, as there was no necessity for it. The deceased had no occasion to work by means of a can, as the working was supplied with oil by means of a lubricator, could only account for the occurrence by the fact that the deceased in feeding the crank had his shirt or coat caught in the machinery and got whirled round the crank wheel. In his statement the engine been fenced in, it would not have prevented the accident. The deceased had previously been cautioned not to place his hand on the crank-bearing as he was in the habit of doing. The fault of the unfortunate man is evidently to be attributed to his own carelessness and not to any precaution on the part of the employers, or warning from his fellow-workmen, who are liable at any moment to fall victims to wantonly neglect or forgetfulness. An immunity from harm for any length of time renders a man unable to see any appreciable risk in doing that which he has done so often before, and were it not

for the safeguards that are enforced, and the personal supervision usually exercised under these circumstances, the inevitably long list would yet be greatly increased. The recent returns of the inspectors whose duty it is to inquire into the cause and extent of such accidents, show that notwithstanding the care that is taken on behalf of those who will not take care of themselves, the number of accidents does not show any material tendency to decrease. The senior metropolitan inspector has recently stated that many accidents are caused through the inattention of women to their dress. Their loose sleeves and dress come in contact with shafting and driving straps, often inflicting severe injuries, and of course resulting in death at times, whereas if properly fitting garments were worn, and the arms encircled with a close sleeve, many of those accidents would probably have been prevented. It is also shown that in these hurrying and driving times, that a large number of accidents are caused by the eagerness of workpeople to get through their work, and workers are urged on by overlookers who are interested in the quantity turned off. Competition, healthy and desirable in its way, becomes a curse when human life is put in the scale against a few shillings, perhaps, or even less. But such it is, and being so, too watchful a guard cannot be kept, and the provisions of the Workshop and Factory Acts cannot be too stringently enforced to protect the helpless or careless. These latter have also much to answer for, as many workpeople are injured or killed in consequence of their playing with machinery in motion, wantonly placing in jeopardy their lives and limbs in mere bravado. It has been rightly said that no efforts should be neglected to prevent the deaths and mutilations which seem, by an unfortunate kind of fatalism, to be regarded as an inevitable tribute paid to industry.

THE PUBLIC HEALTH

DURING SEPTEMBER 1884.

THE mean temperature during the month of September at the Royal Observatory, Greenwich, was 59°·3; it exceeded by 2°·8 the average September temperature in one hundred years, and was 2°·5 above that recorded in the corresponding month of 1883. An excess of temperature prevailed on seventeen days of the month, while on the other thirteen days it was below the average. The warmest day of the month was the 17th, when the mean was as high as 70°·0, and no less than 12°·9 above the average; the coldest day was the 4th, when the mean was only 52°·5, and 7°·2 below the average. Rain was measured at Greenwich on twelve days during the month, to the aggregate amount of 2·1 inches, which was 0·3 of an inch below the average September rainfall in sixty-one years. During the first eight months of this year the rainfall amounted to 13·5 inches, which was more than four and a half inches below the average rainfall in the same period of sixty-one years. The sun was above the horizon during 376·9 hours in September, and 119·1 hours of bright sunshine were recorded at Greenwich; this amount exceeded that registered in the corresponding period of any year since 1880. South-westerly winds prevailed during the first week of September, after which until the 21st, the wind was easterly; it was again south-westerly during the last week of the month.

In the twenty-eight large English towns dealt with by the Registrar-General in his Weekly Returns, which have an estimated population of nearly eight millions and three-quarters, 23,080 births and 14,359 deaths were registered during the four weeks ending the 27th ult. The annual birth-rate, which had declined

from 35.5 to 33.3 per 1,000 in the four preceding months, rose again to 34.4 during September, and exceeded by 1.1 the rate recorded in the corresponding month of the preceding year, 1883. In these twenty-eight towns the lowest birth-rates last month were 26.8 in Bradford, 28.3 in Brighton, and 28.4 in Huddersfield; in the other towns the rates ranged upwards to 41.0 in Sunderland, 44.4 in Blackburn, and 45.9 in Newcastle-upon-Tyne. The birth-rate in London last month did not exceed 33.3, while it averaged 35.3 per 1,000 in the twenty-seven provincial towns.

The annual death-rate in the twenty-eight towns, which had been 19.3, 22.8, and 24.2 per 1,000 in the three preceding months, declined to 21.4 during September, owing chiefly to the decreased fatality of diarrhoeal diseases; this rate, however, exceeded those recorded in the corresponding months of 1882 and 1883, which were 20.3 and 19.5 per 1,000 respectively. The lowest rate of mortality last month in these towns was 15.6 in Brighton. The rates in the other towns, ranged in order from the lowest, were as follow:—Derby, 16.5; Birkenhead, 17.5; London, 17.7; Portsmouth, 18.0; Plymouth, 19.5; Bristol, 19.7; Huddersfield, 19.7; Bradford, 22.3; Oldham, 23.5; Norwich, 22.5; Nottingham, 23.1; Birmingham, 23.3; Newcastle-upon-Tyne, 24.1; Sunderland, 24.5; Leeds, 25.1; Halifax, 25.2; Salford, 25.3; Sheffield, 25.8; Manchester, 26.6; Liverpool, 27.1; Hull, 27.6; Bolton, 27.9; Wolverhampton, 28.1; Leicester, 28.3; Cardiff, 29.9; Preston, 30.7; and the highest rate during the month, 31.9 in Blackburn. While the death-rate in London during September, as above stated, did not exceed 17.7 per 1,000, it averaged as much as 24.5 in the twenty-seven provincial towns, in many of which diarrhoeal diseases were very fatally prevalent throughout the month. The 14,359 deaths from all causes in the twenty-eight towns during the four weeks of September included 3,275 which were referred to the principal zymotic diseases, of which 2,146 resulted from diarrhoea, 277 from scarlet fever, 254 from 'fever' (principally enteric), 242 from whooping-cough, 183 from measles, 127 from diphtheria, and 46 from small-pox. These 3,275 deaths were equal to nearly 23 per cent. of the total deaths, and to an annual rate of 4.88 per 1,000. This zymotic rate, though it showed a decline from the very high rates in the two preceding months, exceeded that recorded in the corresponding month of either of the two previous years 1882-83. The zymotic death-rate in London during September was but 3.1 per 1,000 (of which 1.6 was due to diarrhoea), while in the provincial towns it averaged as much as 6.4 per 1,000, of which 4.6 was due to diarrhoea. The zymotic death-rates in the provincial towns ranged from 1.9 in Plymouth, 2.4 in Brighton, and 2.6 in Portsmouth, to 9.2 in Bolton, 10.4 in Hull, 10.5 in Blackburn, and 10.7 in Preston.

Diarrhoea was the most fatal zymotic disease in the twenty-eight towns during September. The rate of mortality from this disease in the large towns, which had been 3.67 and 4.97 per 1,000 in the two preceding months, declined to 3.19 during September, but considerably exceeded that recorded in the corresponding period of either of the two previous years, when it was 1.75 and 2.00 per 1,000, respectively. While the diarrhoea death-rate did not exceed 1.56 per 1,000 in London, it averaged as much as 4.58 in the twenty-seven provincial towns, among which it showed very wide divergences; for, whereas the rate of mortality from this disease did not exceed 1.21 in Plymouth, 1.47 in Portsmouth, and 2.05 in Halifax, it ranged upwards in the other towns to 7.21 in Preston, 7.37 in Leicester, 7.77 in Hull, and 8.97 in Blackburn. The death-rate from scarlet fever, which in the two previous months had been 0.44 and 0.38 per 1,000, was 0.41 in September; this disease was much less fatal in London than in the provincial towns, among which the highest rates were 1.24 in Leeds, 1.82 in Sheffield, and 2.09 in Cardiff. The rate of mortality from 'fever' (principally enteric or typhoid),

which had steadily increased in the four previous months from 0.22 to 0.32 per 1,000, further rose during September to 0.38. In London the rate of mortality from this disease did not exceed 0.28 per 1,000, while in the twenty-seven provincial towns it averaged 0.36. The highest proportional fatality in September was shown in St. Preston, Salford, and Hull. The death-rate from whooping-cough, which had steadily declined in the five months from 1.10 to 0.43 per 1,000, further fell to 0.36, which almost corresponded with that recorded in the same period of 1883. In London the rate of mortality from this disease was 0.32, and in the provincial towns it averaged 0.39 per 1,000, equal to 0.64 in Leeds, and 0.99 in Birkenhead. The death-rate from measles showed a further considerable decline from the rates recorded in the three preceding months; this disease was, however, somewhat prevalent in Halifax, Preston, and Bolton. The rate of mortality from diphtheria showed a considerable increase; it was more than twice as high in London as in the aggregate of the twenty-seven provincial towns. During the four weeks of September 46 fatal cases of small-pox were registered in the twenty-eight towns, showing a considerable further decline from the 119 recorded in the three preceding months; of these, 5 occurred in London, 5 in Liverpool, 3 in Sheffield, 1 in Hull, and 1 in Sunderland. Judged by the returns from the Metropolitan Asylums Hospitals, the prevalence of small-pox in London showed a tendency to increase during September. The number of small-pox patients under treatment in these hospitals, which had been 1,000 and 539 at the end of the three preceding months, fell to 536 at the end of September. The average number of new patients admitted to these hospitals had declined in the three previous months from 600 to 536, and rose again during September to 84.

The rate of infant mortality in the twenty-eight towns, measured by the proportion of deaths under one year of age to births registered, was equal to 202 per 1,000 in September, against 172 and 185 in the corresponding periods of the two preceding years, 1882 and 1883. The excess of infant mortality was entirely due to the increased fatality of summer diarrhoea. While the infant mortality in London did not exceed 149 per 1,000 in September, it averaged as much as 242 in the provincial towns, among which it ranged from 138 in Derby, 144 in Portsmouth, 150 in Birkenhead, to 312 in Halifax, 332 in Preston, and 340 in Leicester.

The death-rate from diseases of the respiratory system, judged by the metropolitan returns, was below the average during September. The weekly number of deaths referred to these diseases in London averaged 1.2 per 1,000; the annual death-rate was equal to 2.1 per 1,000. In Liverpool the annual rate of mortality from these diseases was last month equal to 2.4 per 1,000.

The causes of 315 of the 14,359 deaths registered in the twenty-eight towns during the four weeks of September were not certified, either by registered medical practitioners or by coroners. These uncertified deaths were equal to 2.2 per cent. of the total deaths, which was slightly above the average in recent months. In London the proportion of uncertified deaths did not exceed 1.32 per cent. In the twenty-seven provincial towns the average was 2.73 in the twenty-seven provincial towns, ranging from 0.0 in Leicester and 0.5 in Portsmouth, to 4.5 in Sheffield, 4.6 in Huddersfield, and 9.9 in Oldham.

Among the population living in the outer suburban districts around London, estimated to be more than a million persons, the death-rate during September from all causes was equal to 16.8 against 16.0 and 15.5 in the corresponding periods of 1882 and 1883. During the four weeks ending September 15, 170 fatal cases of diarrhoea, 25 of whooping-cough, 23 of small-pox, 20 of diphtheria, 13 of fever, 11 of measles, and 11 of scarlet fever were recorded in the outer districts. These 273 deaths were equal to an annual

3·3 per 1,000, against 2·8 and 2·3 in the corresponding periods of the two preceding years. The fatality of diarrhoeal diseases, 'fever,' whooping-cough, and measles showed a decline; but the recorded cases of small-pox, scarlet fever, and diphtheria showed a slight increase. Of the 23 deaths from small-pox registered in the outer ring 18 occurred in West Ham sub-district (including 4 of London residents recorded in the Metropolitan Asylum Hospital at Plaistow), 3 in Edmonton, and 2 in Croydon. Six of the 13 deaths referred to fever occurred in the district of West Ham; and of the 20 fatal cases of diphtheria, as many as 9 were recorded in the district of Edmonton.

NOTIFICATION OF INFECTIOUS DISEASES.

THE table on p. 157 contains uniform statistics relating to sickness and mortality in twenty-seven of the thirty-nine urban sanitary districts in England and Scotland in which the notification of infectious diseases is compulsory. The population of the twenty-seven towns for which we are enabled to publish complete statistics for the month of September in the subjoining table is estimated at about two-and-a-half millions of persons. The annual death-rate from all causes during that period in these twenty-seven towns averaged 22·55 per 1,000 persons estimated to be living therein. The death-rates were last month considerably below the average in Birkenhead, Burton-upon-Trent, Derby, Edinburgh, Leek, and Reading; while they showed an excess in Accrington, Blackburn, Bolton, Halifax, Jarrow, Leicester, and Preston. The high rates of mortality in these last-mentioned towns were mainly due to the fatal prevalence of diarrhoeal diseases. The death-rate from the eight infectious diseases, concerning all of which, with but very few exceptions, notification is compulsory in these towns, averaged 0·77 per 1,000 persons living in the twenty-seven towns for which this information is available. No death from any of these diseases occurred during September in Hartlepool, Jarrow, Leek, Macclesfield, Reading, or Stalybridge; in the other towns the rates ranged upwards to 0·83 in Nottingham, 0·83 in Edinburgh, 0·86 in Greenock, 1·13 in Dundee, 1·70 in Preston, and 1·85 in Salford. Small-pox caused 1 death in Birkenhead during September; scarlet-fever was proportionally most fatal in Burnley, Preston, and Salford; diphtheria in Dundee; and enteric fever in Birkenhead, Preston, and Salford. With regard to the notified cases of infectious disease in these twenty-seven towns, it appears that the proportion to the population of persons reported as suffering from one or other of the eight diseases enumerated in the table averaged 6·85 per 1,000. While this proportion did not exceed 1·46 in Stalybridge, 2·11 in Warrington, 2·27 in Macclesfield, and 2·28 in Bury, it ranged upwards in the other towns to 8·03 in Birkenhead, 8·39 in Preston, 8·64 in Leicester, 9·66 in Reading, 12·05 in Derby, and 13·96 in Salford. Scarlet-fever showed the largest proportional prevalence in Derby, Halifax, Leicester, Salford, and Reading; enteric fever in Derby, Preston, Salford, Edinburgh, and Greenock; typhus in Salford; and diphtheria in Dundee, Greenock, and Salford. Cases of small-pox were notified during September only in Birkenhead.

WE are requested to state that Mr. R. S. Dunbar, for many years a partner in the Thames Bank Iron Company, has retired from the firm.

AT the annual meeting of the Tweed Commissioners a committee was appointed to make a comprehensive and exhaustive scientific inquiry into the origin, development, and treatment of salmon disease, and £200 was placed at their disposal. The number of dead and diseased salmon, grilse, and trout taken from the Tweed in the last five years was stated to be 37,969.

SPECIAL REPORTS.

THE SEVENTH CONGRESS

OF THE

SANITARY INSTITUTE

OF GREAT BRITAIN,

Held at Dublin from Sept. 30 to Oct. 4.

THE first general meeting of the Sanitary Institute of Great Britain was held in the Theatre of the Royal Dublin Society on Sept. 30. Amongst those present were—Sir Robert Rawlinson, C.B.; the Right Hon. the Lord Mayor and the Lady Mayoress, Dr. Carpenter, President of Council; Dr. Moore, President King's and Queen's College of Physicians; Dr. E. Mapother, Dr. T. W. Grimshaw, Registrar-General; Professor Corfield; Mr. G. Symons; Mr. Rogers Field, Mr. W. Eassie, C.E., Dr. Louis Parkes, Mr. H. H. Collins, Mr. Ernest Turner, Professor Robinson, Mr. George Sykes, Mr. H. Percy Boulnois; Professor de Chaumont, Mr. Wallace Pegg, Mr. Robert O'Brien Furlong, B.L.; Dr. Duffey, and Dr. Chas. S. Cameron, C.S.S.

Sir Robert Rawlinson, C.B., having taken the chair, proceeded to read his presidential address, of which an abridgment is published at page 127.

STATISTIC MEASURE OF THE HEALTH OF COMMUNITIES.

On October 2 Dr. Grimshaw, Registrar-General, read a paper on this subject, of which the following is an abstract:—Undoubtedly the death-rates published weekly, quarterly, and annually by my colleagues in England and Scotland, and by me in Ireland, are *prima facie* evidences of the relative healthiness or unhealthiness of the population living in each of these, and no doubt a very high death-rate does in nearly every case indicate unhealthiness, and a very low death-rate indicates healthiness of the population to which it refers; but it does not at all follow that a death-rate of, say, 40 per 1,000, indicates double the unhealthiness that a death-rate of 20 does. To speak in common parlance, the high death-rate really indicates that the population to which it refers has a delicate constitution, and that with a low death-rate a robust constitution. The prevalence of infectious diseases and their fatality is a very important element in estimating the health of a community; nevertheless, if the death-rate from any particular group of diseases were taken as a single test of unhealthiness, I should choose the constitutional, not the zymotic, group as the most reliable. If we take London and Dublin, for example, and contrast them as to the relative mortality from particular groups of diseases, we find that the deaths from zymotic diseases were 57 per 10,000 of the population in Dublin, and 51, or but slightly greater in the former than in the latter, in London; whereas the death-rate from constitutional diseases in Dublin was 43, while in London they were only 23, or little more than one half in the same period. Nevertheless, the total death-rate in Dublin was 277, while in London it was 230, or 47 less. Again, the infantile death-rate is much relied on, but a low infantile death-rate is quite consistent with a high general death-rate, as, for instance, happens to be the case of Dublin, where the general rate of mortality is high, but the infantile mortality is comparatively low. Attempts have been made from time to time to estimate what should be the death-rate of a healthy community, but in my opinion all such efforts have been failures, and we are driven to depend upon comparisons of death-rates in various countries with one another, or to comparisons of different portions of the same community with the whole or with one another, as the only test of the healthiness or

healthiness of such communities. Thus the average annual death-rate of the population of England and Wales for ten years, 1871-80, was 21.4; while in London was 22.5. In Scotland it was 21.6 for the same period.

Ireland for the same decade it was 18.3, and varied on 27.5 in Dublin to 14.1 in the rural districts of Connaught. Now, do these varying rates truly represent the relative healthiness of the different communities to which they refer? I state, unhesitatingly, they do not: at in some of these districts the people are less unhealthy, other cases more unhealthy, than the rates represent them to be. It has long been known that a very general anomaly existed between the density of a population and its death-rate, in other words, where people are packed closely together that we expect to find a high death-rate. At first sight appears to be a mere truism, but I am glad to say that the old sanitary, or unsanitary maxim, 'that a dense population has a high death-rate,' is coming less true every day, as it has been proved by the operations of artisans' dwellings companies and others who have undertaken to provide dwellings for the working classes, that with reasonable precautions very dense populations can enjoy very good health and have very low death-rates. Unfortunately, however, this old maxim has considerable degree of truth still left, and statistics show that there is a correspondence between high death-rates and density of population. It is a matter of the utmost importance, when applying death-rates as a test of health, that the relative numbers of the population belonging to each social class should be known. The variations in the death-rate between the classes and the sub-classes is remarkable. For example, in the 'professional class' the death-rate is but 19.8 per 1,000, while in the 'general service class' it is 36.8, or nearly double. Among domestic servants it is but 9.1, while among labourers it is 34.4, although both are drawn from the same stratum of society. The number of persons living at different ages differs materially in different communities. From the statistics it would appear that the number of very young people in England is relatively much greater than in Ireland, the number of children under five years being 35.5 per 1,000 inhabitants in England, as compared with 11.3 in Ireland. In the case of infants under one year it is more remarkable, there being 29 'babies' in England to 6.3 in Ireland, a fact which is at variance with commonly received opinions. At the other extreme of life we find that there are more old people in proportion in Ireland where those above 60 number 106.2 per 1,000 of the population than there are in England, where they number about 73.8 per 1,000. Now, as very young children die at a greater rate than older children, or persons in middle life, we might expect the death-rate of England to be much higher than Ireland, but it is only a little higher. And why is this? Because the old people, whose lives are also precarious, are more numerous in Ireland than in England. In both countries the highest death-rate is among children, the deaths under one year being 109.4 per 1,000 living at that age in Ireland, and 152.7 per 1,000 in England, as compared with the general death-rate of 17.4 and 18.9 respectively. The death-rate steadily decreases as age increases, until the age period of from ten to fifteen years is reached, when the rate reaches the maximum both in Ireland and England, being 37 in Ireland and 3.3 in England. It will be observed that in nearly every instance the death-rate of Dublin is somewhat in excess of that of London. In many diseases the excess is small. Thus, in the case of the zymotic diseases, the excess of Dublin over London is not, proportionately, nearly so great as in the case of constitutional diseases. In the former case the ratio is 57.1 to 50.6; in the latter 37.7 to 42.9. Among the constitutional diseases we find that the death-rate per 10,000 from phthisis or pulmonary consumption alone is 31.6, against 25.1, and closely connected with this we find that the death-rate from diseases of the respiratory organs is 55.8 in Dublin, against 47.5 in London.

THE ADMINISTRATION OF THE PUBLIC HEALTH ACT IN IRELAND.

Dr. Edgar Flinn, surgeon to St. Michael's Hospital, Kingstown, read a paper on the administration of the Public Health Act in Ireland with regard to the duties of the officers of health. He said the working of the Public Health Act in this country has, in a great majority of districts, well-nigh become a dead letter. One of the main causes of the slow progress of sanitary reform in Ireland is that there are no local boards or combinations of districts. The boards of guardians, the sanitary authorities for the rural districts, are not, as a general rule, opposed to sanitary reform, yet they are never anxious to move in any measure of sanitary work that will cause outlay. The reports of medical officers of health are frequently left unread, and treated as waste paper. In England such reports are read, discussed, and their suggestions promptly acted upon. The indications were numerous that the Local Government Board in Ireland would soon have seriously to take up the question of combinations of districts and unions for the appointment of a medical officer of health. In lieu of having six or more medical officers of health in each district, with a superintendent medical officer of health, there should be one, and only one, medical officer of health, who should be a man free from the cares of practice, and whose pecuniary interests would not be perpetually at war with a due and fearless discharge of his duties.

The writer had often heard it said by medical officers of health that they were unable to carry out the Public Health Acts in their districts. In the smaller towns in England greater attention is paid to the sanitary laws than in similar towns in Ireland. In small towns in Ireland, where the town revenue is, perhaps, not much over 50£, the whole of this sum is paid away in salaries of officials, and there is nothing left to be applied to the practical carrying out of sanitary improvements. He could confirm the observations that had been made, that sanitary administration is not properly carried out in most of the small towns in Ireland, and in some of them it is not carried out at all.

Mr. Edward Spencer, M.A.T.C.D., Secretary to the Dublin Artisans' Dwellings Company (Limited), read a paper on—

THE HOMES OF THE WORKING CLASSES IN DUBLIN.

After noticing the difficulties in dealing with the subject by general as distinguished from local legislation, and pointing out that Dublin is, of all cities which have carried out improvements for the housing of the poor, most peculiarly situated, Mr. Spencer proceeded to discuss his subject from a local point of view. In 1871 there were, he said, out of a total number of 58,327 families in Dublin, 44,933, or 77 per cent., living in 10,954 tenement houses, being 4.1 families to each house—the term 'tenement' being applied to all houses, of whatever size, accommodating more than one family. In 1881, out of 54,725 families, 39,997, or 73 per cent., lived in 9,854 tenement houses, or 4.05 families per house. The number of persons to each family had, however, increased from 4.2 in 1871 to 4.5 in 1881. Of 1,100 tenement houses which have disappeared, 1,053, occupied by 4,659 families, contained more than ten rooms, and from two to six families each. It is certain that this decrease would have been much larger but for the constant supply of first-class single houses which have lapsed into tenement houses. The figures also show that while the decrease of families of all classes amounted to 3,538, those occupying tenement dwellings have decreased by 4,948, and that the difference represents 1,413 families who have advanced to single house accommodation. On the whole, continued the writer, we have the broad fact that in 1871, 77 per cent. of the families in Dublin, or 188,769 persons, lived in tenement houses, and that this proportion

was only reduced to 73 per cent., or 182,278 persons, in 1881. With reference to the condition of these houses, it was sworn before the Royal Sanitary Commission on Dublin in 1879 that of 9,760 which then existed, 2,360 were unfit for human habitation, 3,500 were repairable, and 4,000 in a better condition. The want seems, therefore, to be of two kinds—the demolition of old and substitution of new buildings, and the proper maintenance of existing dwellings. Everyone who knows Dublin will be struck by the large number of abandoned houses to be seen in comparatively respectable streets, and will not fail to observe the gradual injury inflicted by the condition of such houses on the adjoining ones. A great many of these houses have been closed by the medical officer of health as unfit for human habitation, or by the surveyor as structurally dangerous. If the medical officer of health and the surveyor certify that the building is past repair and requires demolition and reconstruction, the owner or the local authority must take it down. The decision of these officers is final, and there is no appeal. If the owner elects to take down the house he may leave the site vacant if he wishes, but self-interest will be a sufficient guarantee in that respect. He can, however, call on the local authority to purchase the premises, in which case that body must take down the house, and may either erect labourers' dwellings or lodging-houses, dedicate the site to public health, or sell or let it without any special restrictions. For either of the first two cases they may borrow public money, but no greater rate than 2*d.* for one year can be levied. The purchase money is to be fixed by agreement or arbitration, and there is no appeal against the arbitrator's award. The greatest bar to the improvement of the homes of the working classes in Dublin is the present anomalous condition of the valuation of property. This affects not only the provision of such dwellings, but the improvement of every class of buildings. The shortest way of indicating the present state of affairs is to give an example from each kind of property, although it might be sufficient to state that there has been no general revision of the valuation of the city for thirty-five years. There have been five commercial houses, in the vicinity of the leading business thoroughfares, lately rebuilt at a total cost of 12,750*l.* Before their reconstruction their valuation amounted to 532*l.*; now it is 925*l.* Taking the rates and taxes at 10*s.* in the 1*l.*, the increased annual expenditure of the five investors under this head was 196*l.* 10*s.*, or, at twenty-five years' purchase, 4,912*l.* 10*s.*, or 38½ per cent. on their outlay on buildings. Passing to the homes of the working classes, and selecting at random seven tenement houses in various parts of the city, and seven improved dwellings, the valuation of each being the same, viz. 9*l.*, or 63*l.* for all, the annual rental of the old houses being 322*l.*, of the new 118*l.* That is to say, the proprietors of the tenemental dwellings contribute 10 per cent. of their income to the rates, while the owners of the new dwellings pay 27 per cent. of their income to the rates. This inequality presses on the very class we are supposed to be benefiting, as the following facts will show. Mr. Spencer has investigated the present and former rents paid by 427 of the tenants of the Dublin Artisans' Dwellings Company, and finds the present rent to average 5*s.* 3*d.* per week, the former rent 4*s.* 3*d.* Dividing these gross rents into the two items of 'rent' and 'taxes,' and applying the proportion of taxes to rent given above, it will be seen that the 'rent' of the new dwelling is 3*s.* 10*d.* and taxes 1*s.* 5*d.*; while the 'rent' of the tenemental dwelling is 3*s.* 10*d.* and taxes 5*d.* It will therefore be seen that the extra price which the tenant pays for the improved accommodation is made up entirely of increased taxation. As the writer was anxious to illustrate the necessity for preventing the alteration of single dwellings into tenement-houses (either under the Public Health or Torrens's Act, or, if necessary, by new legislation), enforcing structural alterations necessary for its converted state, he selected a house at random in one of the finest thorough-

fares in Dublin, and which has been converted during the past year into a tenement-house, and, through the kindness of Dr. Cameron, medical officer of health, he is enabled to place on record its present condition. The house is occupied by nine families, but is in good order; the cubic space per head is not less than 300 feet, and the house may be taken as a very favourable example of the tenemental dwellings in Dublin. Six rooms are occupied by as many families, containing forty-seven persons, and three rooms are occupied by three families, containing eight individuals. In the back kitchen live a family of six—father, mother, and four sons, the eldest of whom is 17, the youngest 10. The second floor front room is occupied by a family of ten, of which two are men over 25, two boys from 14 to 16, and three women from 23 to 40. In the top front room live another family of ten, comprising two males, one 19, the other 40, and four females, aged 10, 12, 14, and 36; and in the top back live a man, his wife, her mother, and a baby. All of the other rooms are occupied by families with children under thirteen years of age. With those houses which have already been converted without any structural alterations the task of the sanitary authority is much more difficult. While a large number of tenement house owners systematically evade the law in Dublin, there is a large number who honestly endeavour to do their duty, and to encourage whom should be the policy of the sanitary authority. The proceedings necessary to get rid of a tenant and get possession, before the Court of Summary Jurisdiction, occupy five weeks at the least, and practically involve the loss of seven weeks' rent; and the proceedings necessary to get rid of a tenant who pays more than 4*s.* 6*d.* a week occupy on an average three months. During all this time no rent is paid, and the property of the unfortunate owner is liable to the grossest injury without any practical means of redress. It is a well-known fact that there are tenants in Dublin who go from tenement to tenement, never paying one week's rent from year to year, and very often getting money from the landlord to give up possession. The condition of the law on this subject is one of the greatest practical bars to the improvement of the dwellings of the working classes. Within the past eleven or twelve years accommodation has been provided for 2,857 families, representing about 16,000 persons. Although the necessity in Dublin for the demolition of old, substitution of new, and adaptation and maintenance of repairable dwellings is exceptionally great, it must be admitted that within the past few years special efforts have been made, both by the local authority and by public and private enterprise, to meet the necessity, and it is worthy of notice that Dublin is one of three cities in the United Kingdom which have carried out more than one improvement scheme under Sir R. Cross's Acts.

Mr. J. Wycliffe Jones, surgeon-major in charge of Her Majesty's troops at Naas, read a paper on—

THE INSANITARY STATE OF SMALL IRISH TOWNS.

The author said: The deplorably insanitary condition of several small Irish country towns, in which during various periods of my service at home it has been my lot to be stationed in medical charge of Her Majesty's troops, has impressed me so forcibly that I feel moved to submit a brief paper upon the subject.

The fact that the statistics available deal with the sickness and mortality of small towns, only as they form a part of a large rural district, precludes the possibility of fixing the amount of sickness and mortality chargeable to the town itself apart from its surrounding rural district. I feel strongly convinced that the death-rate must be high in many towns I have known, yet upon an examination of the statistics of the area into which such towns were collated I have been astonished to discover a very low rate of sickness and death. This statistical imperfection has a further important bearing: I cannot in justice con-

on the condition of things in any one town as exceeding, evil case, those of any other, for, again, I am unable to give my case. For instance, although the insanitary state of Naas—my present station—is so bad, so deplorably bad, that every essential for healthy life is absent, I cannot state from personal observation nor can I prove figures that its condition is in any degree worse than that of many other towns I have formerly resided in. I must therefore be content to furnish a brief epitome of the results of several years' observations, dividing these under the several heads of—

(1) Overcrowding. (2) Particular descriptions of dwellings, and rent. (3) Sewerage and conservancy. (4) Water supply. (5) Ablution. (6) General habits and state of the people, and intemperance.

Overcrowding.—In a most wretched, half-ruinous, two-storyed house, containing four simply shocking rooms, I and four families resident—in all, twenty-two souls. My visit—made for the dispensary physician, absent on leave—had for its object the relief of a poor woman in her confinement; and this took place in one of the smallest and worst rooms in this terrible abode, and under such circumstances of appalling squalor and deficiency as made her subsequent recovery a matter of astonishment to me. Another instance: to everyone who has any knowledge of Ireland the form of the Irish cabin will be familiar; be outer room, or kitchen, and the inner room—'the room' *par excellence*; both floors are clay usually, and the levels lower than that of the street. In winter, damp prevails, but one fireplace is provided, and this utterly devoid of any description of grate. Let us, then, imagine two to three families huddled together upon the two floors.

Other instances will be interpolated between particular descriptions of dwellings, as an essential to that division of the subject, but I am convinced that extreme and cruel overcrowding is a widespread sin of Irish country towns.

Particular Descriptions of Dwellings.—The Irish dwelling is of two classes: the one-storyed clay-floored cabin—I cannot with truth use the cheerful English word 'cottage' very often in Ireland, cottages are far too scarce—and the two or more storyed house.

I believe that these latter will be usually found to furnish instances of a lower degree of insanitation than even the cabin—vile though it be—and this seems partly to be the result of a belief in the unlimited capacity of any dwelling that possesses several floors. Even though the ground floor be rather crowded by the wretched 'deputy sub-assistant landlord,' his family and guests, there is always 'plenty of room upstairs,' or rather, 'above in the rooms'—'above' conveying to the Irish imagination an almost unlimited degree of storied elevation, provided that the two, four, or sixpence per night be forthcoming. Again, too, the police cannot so easily penetrate, nor can the members of that stalwart corps feel very safe upon the crazy stairs.

The worst descriptions of dwellings are usually to be found hid away in lanes and courts behind the main streets. I will endeavour to describe a small court of dwellings very recently visited. The entrance is in a narrow lane of cabins, and this opens to the main street of the town. Picture then a horrible little courtyard some 50 ft. \times 28 ft., almost completely enclosed by small dwellings; the ash-pits, pigstyes, and back yards of the front row of hovels forming the only prospect possible for those inside the court. The entire block of building does not occupy, to the best of my judgment, nearly one rood of land, nay, indeed, the one-sixth of an acre. Upon this site are built thirteen simply frightful dens, all have damp or clay floors; pools of green and black water lie all around, black typhoid mud, and festering manure in abundance. Some fifty-five to sixty souls live in this court, and many pigs are kept. I measured several, and append a few results. No. 1 house, $5'7" \times 14'2" \times 6'9" =$ cubic ft. less than 588; four souls live here. No. 2, $15'7" \times 12' \times 9'6" =$ cubic ft. less than 1,800; five souls resident. No. 3, $15'7" \times 10'8" \times 9'6" =$ cubic ft. less than 1,500, and eight souls resident.

In the first about 100 cubic feet of foul damp air could be enjoyed, in the second about 300, if no lodgers come for the night, in the third about 142. For the worst description of dwelling 1s. to 1s. 6d. per week is paid, but 2s. 6d., 2s. 8d., and 3s. is very commonly demanded even for cabins, which can, with truth, be described as 'unfit for human habitation.' A very wide field of observation, both in Europe and in India, has not furnished me with any parallel to all this. In no country on the globe has human misery reached so low a degree of degradation. Picture what life must be in such dwellings, and be well assured that I furnish no isolated instance, but a true representation of what is all but universal in Irish country towns.

The worst dwellings are to be found in towns owned by a number of small proprietors. In these, sub-letting of even fairly good houses is carried to a ludicrous degree. A bachelor friend of mine once obtained, with difficulty, in a small country town, two furnished rooms in the same house; but he rented his sitting-room from one landlord, and his bedroom from another. Again, in the instance mentioned of the house in which I found twenty-two souls, two or three landlords were part owners, and the third, *i.e.* who occupied one room—himself and family—drew 8s. 6d. per week from three sets of squalid lodgers. The house pays to various owners about 34s. a year, when quite full. I would be sorry to give that sum for the materials of which it is built.

Sewerage and System of Conservancy.—My experience leads me to the strong belief that under this head every sanitary rule is almost universally violated. Having regard to the towns at large I am unable to remember one where an efficient system of drainage and sewerage exists.

Latrines, &c.—Then, as to latrine accommodation, it is notorious that none whatever is provided for a very large number of the humbler dwellings in Irish towns; while even houses of a better class are vilely provided. The state of deplorable degradation engendered cannot be exaggerated. Connected with this subject I must speak of the intense nuisance created in the horrible labyrinth of back yards seldom absent in Ireland. Here pigs and horses are kept; often, too, no back-lane entrance exists, and at potato sowing time I have often seen two or three cart-loads of festering black typhoid sludge and manure conveyed through, not one or two, but many dwellings, and thrown in a large heap upon the main street, until carted away; the unspeakable stench at the back, inside, and in front of the house may be imagined.

I would say a word about slaughter-houses, and shall describe one. In a minute yard, entirely hemmed in by buildings, whose back windows open upon it, hundreds of sheep and cattle have during many years been slaughtered; no back lane gate exists, the beasts are driven in to their death through the street door. A slight whiff from this fearful den has sufficed to produce in myself severe nausea. This is a fair sample, for all I have seen are very similar.

Water-supply and Means of Ablution.—The source is usually pump wells, and the quality is not prominently bad, but the quantity is often scanty, and always insufficient, for those living far from a pump, hand-carriage being the rule, a cruel labour generally imposed upon the young.

The means of ablution are of the humblest; dirty water is thrown into the kennels, and what with overcrowding and clay floors, extreme personal uncleanness prevails.

On October 2 Mr. Cotton, C.E., read a paper on—

THE OPERATION OF THE PUBLIC HEALTH ACT (IRELAND).

He discussed at considerable length the operations of the Public Health Act (Ireland), 1878, in so far as it related to engineering, confining his remarks to the operation of the Act in respect of sewerage and sewage disposal and water supplies. Upon these points he said:—Since the power of sanctioning loans for sanitary purposes was given to the Local Government Board for Ire-

land, loans for various purposes under this Act have been sanctioned to a large amount. In the nine years ending March 1884, the total amount of such loans was 1,206,419*l*. Of this about 700,000*l*. was sanctioned for waterworks, and 230,000*l*. for sewerage works. Loans to the extent of over 100,000*l*. have been sanctioned for paving streets and flagging footpaths; the balance consists of loans for labourers' and artisans' dwellings, new streets in Dublin, town halls, cemeteries, baths and washhouses, scavenging, &c. Although there has been a great improvement in the water-supply to towns in Ireland generally, there are still cases of important towns which are badly in want of new supplies or considerable improvement of the existing supplies. The sanitary authorities of the smaller towns where deficiencies admittedly exist are frequently discouraged by the fancied, because unknown, extent of the responsibility they may assume, and expenses they may be led into when once they embark on such an enterprise as a 'waterworks scheme.' In the urban towns of the first class, with populations of from 2,000 upwards, the cost of the waterworks is from 2*l*. to 3*l*. and more per head, but does not exceed the annual valuation. In the urban towns of the second class the expense of the waterworks had been, or will be, under 2*l*. for each resident, but exceeds one year's valuation. The rates of interest for sanitary loans from the Board of Public Works vary with the time when the loan is repayable—viz., for a loan of fifty years it is 4½ per cent. per annum; for forty years, 4 per cent.; for thirty years, 3½ per cent.; and for twenty years, 3 per cent. All such loans must be repaid by equal half-yearly instalments of the principal with the proper interest on the then outstanding balance of principal. The annuity system, or that of repayment by equal annual payments over the entire term of the loan to cover repayment of principal and interest, does not now apply to sanitary loans. Loans for waterworks are usually sought for the longest term which the Commissioners of Public Works can give—i.e. fifty years. It does not appear that there is any great advantage in this. The initial rate for a fifty years' loan is only a fraction less than that for a forty years' loan; and in seventeen years, before half or even the shorter term has expired, the rates to be paid for each loan are identical, and from that year out the shorter loan has the advantage of entailing lower annual rates, besides being entirely wiped out in the fortieth year, when there are still ten years remaining encumbered with payments on account of the fifty years' loan. Filtration has not been provided for in all cases. Generally speaking, this has been from the wish to keep down the expenses, but they have only been omitted where there was no decided reason for the water being filtered. Only two loans have been sanctioned for providing filtering arrangements after the completion of the rest of the works, and no other application has been made. The improvement of the sewerage arrangements in towns has attracted perhaps more attention than that of the water-supply, at least since the Local Government Board were first empowered to sanction loans for sanitary purposes, the applications for sewerage loans have been more numerous than those for loans for waterworks. This arises partly from the necessity where it exists from improvements in the drainage of towns coming more readily home to the minds of the ratepayers, and partly because the burden of taxation entailed by such works is usually small compared with the taxation necessary to meet the charges of a waterworks loan. The number of sewerage loans has been swelled by numerous applications during the period of distress in 1880-81, with the object of combining relief through the employment of labourers with utility in the work on which they were to be engaged. The result was that applications flowed in for small loans for sewers in villages and hamlets, which would probably otherwise never have engaged the attention of their respective sanitary authorities. Of course very many of the works executed under such circumstances presented a minimum of utility; indeed, it was not easy to stretch the meaning of the word 'sewers' to include

some of the drains proposed, but every latitude was given, and on the whole I am convinced that a vast amount of good has been effected by the works of this kind, the execution of which was prompted by the desire to afford relief to distressed labourers, and encouraged by the low rate at which the money was lent by the Government. The question of the disposal of the sewage continually presents difficulties in dealing with applications for sewerage loans. There is a widespread opinion that the sewerage of a district should follow the rain water to the nearest stream by which it will be carried off—a very convenient system for the district in question, but inconvenient to its neighbours down stream. The law is now so explicitly stated by the 19th section of the Public Health (Ireland) Act, that sewerage schemes in which this method of disposal of the sewage is adopted cannot be sanctioned and are invariably rejected. The disposal of small quantities of sewage on osier-beds on swampy margins of rivers has been suggested; but this method has not, continued Mr. Cotton, that I am aware of, been adopted in Ireland. I should like to see it get a fair trial here. The larger the town the greater the difficulty of dealing with this question, though when the authority is an urban one it has greater facilities for carrying out anything requiring supervision. Ventilation, in connection with a sewerage system, is now recognised generally as an essential; and no sewerage loan will be sanctioned unless the ventilation of the sewers is provided for. There is a prejudice in many towns against free ventilation in the streets, and recourse is had to ventilation by means of piping carried up the houses, but in the principal towns the ventilators open directly in the street surface. With regard to the effect on the rates of the improvements in sewerage arrangements, I find that in but one or two cases has the initial sewerage rate exceeded sixpence in the pound: it varies from twopence to sixpence. Loans for sewerage works are repayable by instalments and interest, in not more than thirty years. Other loans than those I have been referring to have been sanctioned under the Public Health (Ireland) Act, 1878, to a considerable amount. Over 80,000*l*. has been sanctioned for the construction of new streets in this city, which not only are a direct advantage in facilitating traffic, but also aid indirectly (but largely) in improving the health of the place by clearing unhealthy areas and opening fresh air spaces. Over 130,000*l*. has been lent for paving and flagging streets and footways, by which their state—from a sanitary point of view—has been greatly ameliorated. New cemeteries have in many cases been provided by provisional order for the acquisition of the sites for them, and by loans for the construction of the structural works. Loans have been made, but only to small extent, for disinfecting chambers and baths and washhouses. Perhaps the experience derived from the washhouses now in course of construction in this city may lead to their further development. Loans of some magnitude have been sanctioned for town halls, markets, gasworks, &c., which only slightly bear on sanitary matters. Large loans have also been sanctioned by the Local Government Board under the Artisans and Labourers' Dwellings Act. An Act of Parliament was passed last year which, it is to be hoped, will be attended with very beneficial results to a large number of the labouring class. I refer to the Labourers (Ireland) Act, 1883. It would be premature for me to say more than that provisional orders confirming schemes made by rural sanitary authorities for the erection of over 3,000 houses have been issued by the Local Government Board. The loans which will be required for these will exceed in amount 300,000*l*. Though the works to which I have now briefly alluded as being directly, or indirectly, connected with the operation of the Act of 1878 and its predecessors may not present a large total in the eyes of any one conversant with the long lists of similar works under similar Acts contained in the reports of the Local Government Board in England, I think all

7. Essie read a paper on 'THE COLLECTION AND DISPOSAL OF HOUSE REFUSE,' published at 7.

2. *Street Scavenging and Watering.*—There are in all about 113½ lineal statute miles of streets within the municipal boundary of Dublin. In 1883, 27,000,000 gallons of water were spread on the streets, and 100,748 loads of scavenging were removed, 36,645 from paved streets, lanes, and markets, and 64,103 from the macadamised streets and roads. In this section of the work 224 men, including foremen, and 63 horses are employed. We have ten

horse-drawn sweeping machines in use, with which all the principal streets are swept by night; the back streets and lanes are swept with hand brushes by day. The horse-brushes turn out at eleven o'clock at night, and the day scavengers commence work at 4.30 in the morning, the carts turning out promptly at five o'clock to water or scavenge as required. The asphalted streets are washed regularly with hose; all the first and second-class streets are cleansed daily, and the third and fourth-rate streets are done three times a week. The lanes of Dublin require and receive quite as much attention as the main streets, on account of the quantity of vegetable and other refuse which is thrown upon them. The abatement of this nuisance, however, has of late received considerable attention from the chief commissioner of police.

3. *The Removal of Night Soil and Domestic Refuse.*—This section of the work, commenced in May 1882, is now fully organised, and a staff of 110 men, including foremen and 39 horses are employed. During the present year the quantity of house refuse removed per day has exceeded 250 tons. The cleansing of the ashpits is done by night—that is between the hours of 10.30 P.M. and 9 A.M., and the men are paid according to the weight of refuse removed. When the domestic scavenging was undertaken there were in the city 18,165 ashpits, of which number more than one-half were wet sunken pits, and in addition there were 11,577 common privies. From more than 10,000 ashpits the refuse could be removed through the house only, and from 13,000 ashpits the refuse had to be carried out in baskets or buckets. The regular and systematic cleansing of these places revealed in full the necessity for structural and other improvements. The abolition of privies in all the main streets was first accomplished, and subsequently a system for the daily removal of the shop sweepings and house refuse therefrom was organised. Galvanised iron dustbins, suitable to the respective requirements of the shopkeepers and householders, are supplied by us at cost price. Three different sizes of covered bins are used for the collection and removal of shop sweepings and dust by the morning bell-carts, and an oblong open bin is supplied for the reception and removal of house refuse. There are already more than 2,000 dustbins in regular use, and the number is rapidly increasing. Having insisted on the use of dustbins of a uniform pattern from the commencement of this branch of our domestic scavenging, Dublin has been spared the nuisance caused by the use of orange boxes, tea chests, hat boxes, and such articles, which are still commonly exposed with house refuse in nearly all large cities.

Thus there are two systems in operation: portable dustbins and fixed ashbins or ashpits. The former system is extending in the centre of the city, where fixed ashpits are being gradually abolished. The latter system, however predominates, and the great bulk of the domestic refuse of Dublin is still collected in ashpits.

During the last two years about 3,000 privies have been abolished, and a corresponding number of water-closets have been erected. There are now about 18,000 water-closets in use, so that in a few years more we hope to see Dublin a water-closeted city.

The removal of excreta by water carriage has its weak points like any other system, still I feel certain that it is the best that could be adopted for Dublin, considering its proximity to the sea, its abundant water supply, and efficient system of main sewers. While the excreta, the most noxious, but at the same time the most valuable of the domestic refuse, is thus got rid of by means which sanitary science considers the cleanest, quickest, and best, the remainder of the house refuse becomes to a large extent valueless as manure, and a large portion of it is altogether unsaleable.

A brief description of the arrangements for the disposal of the city scavenge, saleable and unsaleable, is subjoined.

The total quantity of scavenge removed during the year 1883 was as under:—

Scavenge from Paved Streets, Lanes, and Markets	36,645 loads.
Do. from Macadam Streets and Roads	64,103 "
House Refuse from Ashpits	71,476 "
Do. from Portable Dustbins	2,201 "
Total	174,425 loads

The saleable scavenge or city manure is composed of the scavenge from paved streets, lanes, and markets, the wet ashpit refuse and night-soil, and amounts in round numbers to 75,000 loads per annum. The unsaleable scavenge, or city refuse, consists of the scavenge from macadamised roads, dry ashpit refuse, and the contents of dustbins, amounting in all to no less than 100,000 loads yearly. To dispose of the saleable scavenge advantageously, as it is produced, in the least objectionable manner, and to get rid of the unsaleable scavenge by the most rapid, efficient, and economical method possible, a variety of circumstances must be considered.

In Dublin, Mr. Young said, we are confined to the farmers around the city, who draw the manure in large quantities from the depôts, and to those having land convenient to the canals, by which we now despatch a considerable quantity annually. But we have no railway traffic in manure, and on the whole the demand for city manure in the country districts is slow, and the prices obtained for it so very low that it was apparent, from the commencement of the domestic scavenging, that any scheme which would involve the riddling of the refuse, and its preparation as a manure, would not yield a revenue which would justify the expenditure. Besides, in the Dublin refuse the proportion of heat-giving cinder is so very small that it would be inadequate to produce the steam-power required for the riddling and preparation of the manure as carried on in Glasgow and Manchester. I shall now describe briefly the arrangements at one of our manure stations. Stanley Street, which is the only manure depôt on the north side of the Liffey, was purchased in 1882, and extensive buildings have since been erected there by the cleansing committee. On the east side of the ground is the stable yard, with stables for eighteen horses, forage and harness rooms, cart-shed, foremen's offices, and stableman's house. At the entrance gate is the yardman's house and weigh-office, which has telephonic connection with the offices of the department on Wood Quay. From the weigh-bridge a paved inclined roadway, 30 feet in width, provides easy access for the dust-carts to the upper floor of the manure-shed, which covers a space 154 feet in length and 78 feet in width. Within this building the refuse is tipped, mixed, and again despatched by the farmers' carts, which remove in rotation the manure from the three bays into which the ground floor is divided. Cinders and other combustible refuse, valueless as manure, are passed through the cremating furnace, which stands conveniently in a separate building at the end of the manure-shed. Old iron, leather, bottles, &c., are also collected for sale.

In order to prevent the escape of noxious odours, special attention has been given to the ventilation of the main building. The foul air is conveyed under the bars of the cremating furnace, and is thus purified before passing into the chimney, which is 140 feet in height. The yards, incline, and floor of manure-shed are paved with granite sets on a concrete foundation, so that the whole premises present a clean and orderly appearance. To the work as now carried on there has been no complaint, nor is there the slightest cause for objection. The amount expended at Stanley Street on the purchase of the ground, erection of buildings and paving, has been 7,850/.

The saleable refuse dealt with at our three manure depôts forms about three-sevenths of the whole scavenge, so that we have about 100,000 loads of unsaleable scavenge to dispose of annually. Regarding this class of refuse, the consideration is what is the cheapest and best

method of getting rid of it at once and for ever? I am glad to state that we have decided to convey the Dublin unsaleable refuse to sea in a hopper barge.

The cost of this vessel will be 5,950*l*. She is specially designed to meet all our requirements, and is now almost ready for launching. A suitable and convenient berth has been obtained on the river near the Swivel Bridge, and is now dredged out to the required depth. A jetty, 120 feet in length, and 16 feet in width, has been there built, and upon it a five-ton steam crane with novel and efficient loading appliances has been erected for the purpose of transferring mud as well as dry refuse direct from the scavenge carts to the barge, with which we propose to commence operations in a few weeks.

The following are the principal dimensions of the vessel :—

	Ft.	In.
Length	116	6
Breadth, moulded	30	0
Depth moulded, amidships.....	12	0
Length of hopper	50	0
Breadth.....	18	0
Sheer, forward.....	2	9
„ aft.....	1	6
Camber of deck	0	6

She will carry about 340 tons of refuse, and the trip to the place of deposit off Howth and back will take less than five hours in average weather. By this means the refuse will be conveyed to its ultimate destination at an estimated cost of fivepence per ton.

TENEMENT HOUSES.

In nearly all our large cities, Dublin not excepted, the material change caused by the exodus of the better classes to rural or suburban residences has necessitated alterations in the urban houses now occupied by the lower classes, and more especially improvements in the sanitary accommodation provided for them, but in many instances these improvements have not been effected.

The drains, closets, ashbins, water-supply, and paving in the yards connected with the tenement houses forming the dwellings of the working population are frequently defective or inadequate. In every tenement yard there ought to be—1. A proper house-drain not less than 9 inches in diameter, carefully laid with a proper fall to the main sewer, and properly jointed. 2. A large gully-trap connected with the sewer for the reception of slops. 3. Two closets, one for each sex, with a cistern capable of containing not less than four gallons of water. 4. A covered ashbin not less than 5 feet by 4 feet by 2 feet 6 inches. 5. An impervious surface of asphalt, or paving sets grouted with tar, laid with a proper fall to the gully-grate. And 6. In addition to the ordinary water-tap, a tap to which a hose can be attached for washing out the yard should be provided.

With regard to water-closet accommodation, in the absence of compulsory power, it is a difficult matter to induce landlords to go to the expense necessary to provide good substantial closets, with cisterns sufficiently large, and adequate sewers laid as they ought to be; when all these have been provided, it is still more difficult to train a population to use water-closets without abusing them; and it is discouraging to householders to find closets broken or choked with rags or straw soon after erection. Yet withal we regard the water-carriage system as the cleanliest and best that can be adopted in a city circumstanced like Dublin, but at the same time we regard strict supervision over the erection of the closets with their sewers and water connections as an absolute necessity.

A large gully trap conveniently situated in every tenement yard is also requisite, and, unless such is provided, the slops must find their way into the ashbin, as they frequently do.

I have said that we have both fixed ashbins and portable dustbins in use in Dublin, and the latter system is rapidly extending. The daily removal of house refuse by portable dustbins of a uniform pattern is a system admirably adapted

for the removal of shop sweepings and dry house refuse in the main thoroughfares, and it also works well where you have a population living in self-contained houses or cottages, each provided with a water-closet. But from experience in Glasgow and Dublin, I consider it unsuitable for the lower class tenement houses, where in many cases the people have not yet learned to put the slops into the sewer and the solid refuse into the ashbins.

The fixed ashbins now being erected in the tenement yards of Dublin, at the instigation of the sanitary authority, are calculated to contain the house refuse for one week or thereby. The walls are 9-inch brickwork, the roof galvanised corrugated iron or slates, the floor is from 3 to 6 inches over the level of the yard, and the floor and sides are rendered water-tight with cement. Its advantages are (1) a child can throw refuse into it, (2) it is easily cleansed, (3) no filthy water is allowed to escape and permeate the subsoil, and (4) in the event of portable bins being used at a future date, it will form a stand and shed for them.

Necessary as the sewerage and paving of private yards undoubtedly is to domestic cleanliness, the proper formation and drainage of the public streets in like manner must invariably precede efficient street scavenging. I regard a macadamised street, suitable as it may be for light traffic, quite out of place in the centre of a large city, where no amount of attention will keep it entirely free from its usual accompaniments of dust and mud.

PAVING.

A street calculated to sustain heavy traffic should have a good foundation of concrete carefully laid to the required levels. If the surface is formed of granite sets these should be carefully dressed, so that they can be placed close together, and the interstices should be grouted with cement or pitch. Wooden blocks, well laid and grouted, also make a good street surface, less noisy and more pleasant than granite, for a city that can afford to pay for their frequent renewal. The blocks should be carefully selected before creosoting, otherwise they will wear unevenly. Provided with a good surface of granite or wood, street scavenging, though requiring constant attention, is comparatively an easy matter, and can be efficiently accomplished at a moderate cost.

The vegetable supply of Dublin is a matter which also affects the cleansing operations. An excellent supply of fresh vegetables has created a large demand, and they form an important item in the diet of the lower classes. But, unfortunately for the cleansing department, the cabbages and other vegetables are brought into the city wholly untrimmed and consequently in the height of the vegetable season the department is called on to remove per week not less than 200 loads of vegetable refuse.

Dr. MacCabe, L.G.I., read a paper on—

THE WATER-SUPPLY AND DRAINAGE OF SMALL TOWNS IN IRELAND,

in which he dealt in detail with the difficulty of making arrangements for the supply of pure water for the use of the inhabitants of the smaller towns in this country. He also dealt with the difficulty in arranging the sewerage levels, so as to provide against the pollution of the water courses. The great difficulty was the cost and the limited area to which taxation could be applied. He suggested that the cost should be so divided as to fall in equal proportions upon a contributory area. His remarks were confined to small urban populations varying between 500 and 6,000.

Mr. H. Percy Boulnois, M.Inst.C.E., read a paper upon—

ISOLATION & VENTILATION.

(Published at page 144.)

DISCUSSION.

Mr. Dodson said that sewerage ventilation would not be perfect until it was arranged upon the same principle as

coal mines. He did not think that rain-water pipes should be used as ventilators.

Mr. Field thought the proposition was a dangerous one.

Mr. Stirling thought that if the exterior ventilation was interfered with, the noxious gases would be sucked into the houses by the heat of the ranges.

Mr. D. Emptage (Margate) saw no objection to ventilation shafts being laid against the houses.

Mr. J. Wallis Peggs advocated the thorough ventilation of the sewers from end to end.

Dr. Carpenter related an instance which had come under his observation where catarrh had been caused by the emanations from an opening in a sewer.

Sir R. Rawlinson said that he had recommended in his recent directions that sewers should be divided into sections. Traps should be provided to prevent the gases in the lower districts from coming up to the higher ones.

Mr. Boulnois, C.E., spoke of the limited number of inspectors which were provided by the Local Government Board, and expressed the opinion that they were entirely too few to do adequately the work required of them. (See SANITARY RECORD for Sept. 15, p. 108.)

THE OBJECTS AND WORK OF THE DUBLIN LADIES' SANITARY ASSOCIATION.

The writer, a lady whose name did not transpire, remarked that it was now fully acknowledged how important was a healthy condition of life for the happiness of the people. It was one of woman's special works to visit the poor, and there was, perhaps, no cause in which woman's tact and sympathy would be of more value than in instructing the poor in the simpler truths of the 'sanitary science.' There were many things which could be noticed by a lady visitor, as a woman amongst women, which would be passed over by regular sanitary officials, or, if noticed by them, perhaps be objected to as an interference and perfectly unheeded. The sanitary inspector could not enter into the question of personal cleanliness, the proper care, clothing, and feeding of children. It must be very difficult for the people to carry out any cleanliness in the dens in which they live, but they must have the knowledge given them and the belief in its efficiency instilled into them before they would even make the attempt. The hardest part of the work was to persuade the lower classes to try cleanliness. The ladies could also act as 'go betweens' between the tenants of those wretched places and the landlords. In fact, the good that might be done by ladies' sanitary associations if efficiently worked, and worked by those who took a thorough interest in them, was incalculable, but great tact and discretion were required. Lest any ladies should be deterred by fear of any disagreeable opposition from becoming district visitors, it was well it should be known that the people were always glad to see them. There were several similar associations founded, and recently one had been formed in Australia. They were all doing good work. The National Health Society had published a large number of pamphlets, &c., on sanitary subjects, and answered a mass of inquiries; and many of the pamphlets were to be translated into Japanese, Chinese, and modern Greek. The National Health Society has also taken up the questions of seats in shops, early closing, playgrounds for children, bread reform, Matrons' Aid Institute, &c. The Dublin Institute had only made a commencement. It was founded in 1881, and the Countess Spencer, who had on every possible occasion shown her sympathy and given her aid to the society, was now its president. Perhaps the most practical and important portion of the work of the association was the district visiting. Unhappily the districts at present worked numbered only two, owing to the want of visitors, which is the more surprising, as happily in this work 'creed' makes no difference. Protestants and Roman Catholics work together with the approval of clergy on both sides. Surely there must be some women in Dublin who are not tied to houses and children of their own to look after, and

who could undertake the work, and find occupation and pleasure in it. Ladies are more easily found as district visitors for other purposes, and possibly it is a better and easier way than for sanitary work; but if it be remembered that 'cleanliness is next to godliness,' and that, in fact, they must and do go together, some would be found to work in the 'straight and narrow way,' which would lead to other and higher work. In conclusion, the writer said her object had been to bring the subject under public notice, and to ask for workers, and not to write a scientific paper, which would be open to discussion.

Dr. Charles Cameron said that a larger proportion of the population of Dublin, which amounted to 250,000, was in a state of more abject poverty than was to be found in any city in England. You could walk for miles in London without meeting a really bad street or a number of dilapidated houses. But you could not pass out of any of the fashionable squares of Dublin without going through streets in which the people were steeped in wretchedness and poverty. That was general throughout this decaying city. The purlieus of Dublin were worse than those of London. It was therefore nonsensical to compare the communities in the two cities. It was surprising to him that the death-rate in Dublin was only 27 per 1,000, and not about 33 per 1,000; and he was happy to find that, though it exceeded the death-rate of London, it was lower than the death-rates of most great cities on the Continent. He heartily approved of the objects of the Dublin Ladies' Sanitary Association. Few were better qualified than he to express an opinion of their work. He had noticed how frequently they had called the attention of the sanitary authorities to neglected places. He thought the large mortality in this city arose from the insufficient feeding and insufficient clothing of the children. This remark applied not merely to the poor, but also to well-to-do people. He had been surprised to find women of the middle class well and comfortably clothed themselves, while the arms and legs of the children whom they were dragging out for their miserable walks were purple from cold. The Ladies' Sanitary Association had a great work to perform, and he was surprised so few ladies were taking an interest in it. Great as had been the work done up to the present, vast was the amount which still remained to be accomplished. Thirty-three thousand out of the 54,000 families residing in the city were living, on an average, in one and a half rooms per family. He thought the best way to improve Dublin would be to improve two-thirds of the inhabitants off the face of the earth. He took some little credit to himself for having by persistent agitation induced the putting in force of the Artisans' Dwellings Act. They could not expect landlords to provide decent dwellings for people sunk in poverty that perhaps they could only pay one week's rent in every four weeks. What he had always contended was that it was the duty of the municipal authorities to provide dwellings for the lowest and most wretched stratum of the population. There were 10,000 people in the city requiring house accommodation who could not afford to pay a rent higher than one shilling per week. Plans were now being prepared, he was glad to say, for the erection of houses upon corporate property which would suit people who could not afford more than one shilling per week.

Sir Robert Rawlinson said it had been one of the tasks of his life to investigate what were called charitable endowments in different parts of the country. These charities had increased to an enormous extent. His observations forced him to say—Show me a largely endowed district and I will show you a corrupt population. Where endowments were relied on, they took away the self-interest of the population to look after themselves. Therefore they must be cautious in attempting to do good that they did not make greater evil. 'Under no circumstances can relief be given in money' was an admirable rule of the Dublin Ladies' Sanitary Society. The question of putting the poor into a proper condition was the statesman's work. The laws must be so regulated, and so framed, and so ad-

at there should be relief without Communism, that nation and to that people who ceased to endeavour, and looked to the ranks above clothe, and take care of them. Its disruption me.

Power, Medical Superintendent, Officer of a paper on

PUBLIC HEALTH OF KINGSTOWN.

There was a very low birth-rate and a relatively low death-rate in Kingstown. The death-rate he excessive, taking into account the very favourable conditions as to health which ought to obtain in a favourably situated. All the physical conditions, namely, the climate, soil, water-supply, and drainage, were good. The first thing that struck him in the causes of the high death-rate was the wretchedness of the slums. These are, for the most part, seen from view by dwellings of a more respectable character, being, in many cases, erected in what were the yards or gardens belonging to the houses. He thought, so that all seems prosperous enough to the casual observer. The number of such hovels and shacks indicates a proletariat out of all proportion to the possibility for employment in such a town. The number of persons in Kingstown constantly on the streets, he believes, completely abnormal even for London, and makes the township extremely sensitive to the effects of 'bad years.' Thus Kingstown presented the worst features of a town of decay, and industry and commerce were almost hopeless.

Mr. Dr. Charles A. Cameron, City Analyst and Officer of Health for Dublin, delivered a paper on 'MICRO-ORGANISMS AND ALKALOIDS WHICH CAUSE POISONOUS.'

Strype, C.E., read a paper on—

PROCESS FOR TREATING AND PURIFYING BLOOD FOR USE AS MANURE WITHOUT CREATING NUISANCE.

In this manner, the writer said, in which the blood decomposes, emitting offensive emanations and odour, has presented considerable difficulty in its use. Blood contains about 75 to 80 per cent of water, which has to be evaporated in order to convert it into a convenient form for agricultural or other purposes. The operation of drying, as usually performed, creates the nuisance by the increased emission of odour. The author's attention had been directed to it in connection with the manufacture of sulphate of alumina, and some of the many sanitary purposes to which this material could be advantageously applied. It is generally known that the ordinary hydrated sulphate of alumina had the property of abating the odour arising from the naturally rapid decomposition of it had been kept for a short time, but the necessary to do so was considerable, and it was impossible to thoroughly mix the sulphate with the blood to secure deodorisation. The treatment with sulphate of alumina has, therefore, not hitherto been a successful one, indeed, much employed on a large scale. Sulphate of alumina, as now manufactured, is insoluble in water, and especially in hot water; that if the sulphate were previously dissolved in water, a solution so obtained could be added so as to be incorporated with every part of the blood. He thought that a small proportion of the hydrated sulphate of alumina, one-fiftieth, or even the one-sixtieth part of the blood, when added in the form of a solution, is sufficient to entirely destroy the offensive odour, and the resulting mixture could be used to prepare it for use in an open pan over a fire or other means without nuisance; the odour emitted during the process of drying is rather less than otherwise, somewhat resembling that arising from a fresh joint of beef. The most

desirable method of adding the sulphate to the blood is to place in a shallow tin dish of suitable dimensions a small quantity of the solution, containing about three-quarters of a pound of the sulphate of alumina, and allow the blood from the slaughtered animal to flow into it. A full-sized animal gives about forty-five pounds weight, or about four and a half gallons of blood. A collecting-vessel is placed close at hand, and the contents of the dishes are poured into it, when it shortly afterwards coagulates, and not the least trace of offensive odour occurs. This method of treatment is now being carried on upon a working scale by the Dublin and Wicklow Manure Company, who collect all the blood from the animals slaughtered at the public abattoir which the Corporation have recently erected in this city. The blood is conveyed to the company's works at Bailybough Bridge, and there dried in an open pan, without the emission of any offensive odour, or the least inconvenience to the workmen, and without any danger whatever to public health. This treatment has also been carried out upon a large scale at some of the slaughtering establishments (or saladeros, as they are locally called) at Monte Video, in the State of Uruguay, where upwards of 500 animals are slaughtered in each saladero per day on the average during the season.

Mr. Francis Parker read a paper on 'THE INFLUENCE OF FOOD ON HEALTH.'

Dr. Charles A. Cameron read a paper on—

THE WATER SUPPLY TO IRISH TOWNS,

in which he stated that in 1881 there were in Ireland eleven cities and towns governed by corporations or town councils. Their aggregate population amounted to 683,502, and their valuation to 1,743,317 $\frac{1}{2}$. The nine townships surrounding the city of Dublin had a population of 95,400, and a valuation of 395,667 $\frac{1}{2}$. There were ninety-four cities and towns governed by towns' commissioners; their population amounted to 449,451, and their valuation to 286,215 $\frac{1}{2}$. The population of all these was, therefore, in 1881, 1,228,357, and their valuation for rating 2,583,435 $\frac{1}{2}$. In such towns the valuation is about two-thirds of the actual letting value. He had endeavoured to ascertain the nature of the water supplies to these 114 cities, towns, and townships, and had succeeded in ascertaining facts regarding nearly every town of importance in the country. The eleven towns governed by town councils were: Belfast—Population, 207,671; valuation, 568,137 $\frac{1}{2}$; water supplied from a reservoir near Carrickfergus, twelve miles from Belfast. Clonmel—Population, 10,519; valuation, 15,424 $\frac{1}{2}$; supplied by local pumps and wells. Cork—Population, 78,361; valuation, 226,022 $\frac{1}{2}$; supplied from River Lee. Drogheda—Population, 12,516; valuation, 28,121 $\frac{1}{2}$; supplied partly by Waterworks Company, partly by local pumps. Dublin—Population, 249,486; valuation, 657,820 $\frac{1}{2}$. The gathering ground of the water supplied to Dublin consists of granite mountains and other high ground, situated about twenty-three miles from the city, in the county Wicklow. The reservoir is very large, and is capable of supplying thirty-five gallons per diem per unit of the population. At first the water impounded had a faint yellow colour, which gradually became deeper, and after three or four years became so deep as to excite alarm. The colour was caused by the peaty and other organic matter in the reservoir becoming soluble by fermentation. After a time the hue became less intense, and now the water is almost colourless. It is soft; one imperial gallon contains about 4 $\frac{1}{2}$ grains of solid matters, 0.0005 grain of albuminoid ammonia, 0.0008 grain of saline ammonia, faint traces of nitrates and nitrites, and 0.96 grain of chlorine. Its hardness is about 10.8, of which 0.8 is permanent. It is one of the purest waters in the world. With respect to pressure and quantity the citizens have nothing to complain. There are some well waters still used in Dublin. They are generally very hard, owing to the presence of large quantities of earthy salts. Kilkenny—Population, 12,182; valuation, 33,155 $\frac{1}{2}$; supplied by local wells, and to a limited extent from river. Limerick—Population,

38,600; valuation, 65,547*l.*; supplied from River Shannon. Londonderry—Population, 28,947; valuation, 74,595*l.*; no information. Sligo—Population, 10,764; valuation, 18,619*l.*; supplied from a lake. Waterford—Population, 22,401; valuation, 39,866*l.*; supplied from hilly region remote from city. Wexford—Population, 12,055; valuation, 16,011*l.*; supplied from pumps. Statistics of a like character were given of towns under Town Commissioners.

Mr. G. B. Nicholls, C.E., read a paper on—

HOUSE DRAINAGE IN CONNECTION WITH TOWN SEWAGE.

He said he had maintained, and still maintained, that all schemes of sewerage should be designed and constructed to receive the house drainage in the most perfect manner, and that so soon as the sewers are ready to receive the sewage the owners of property should be compelled to carry out a perfect system of house drainage and connections to the sewer upon one principle—such principle to be maintained and supported by the authority and under their entire control; and any deviation therefrom should be subject to the highest penalties the Legislature can enforce. The Local Government Board recommended the advance of capital to carry on these sanitary works, and, in doing so, he was of opinion that they would do well to insist that the house drainage and connections should be made to form part of the whole scheme of sewerage, and hold the authority responsible for this work, which in every instance should be carried out under the supervision of thoroughly qualified officers. If such a state of things could be accomplished under some enactment, we should have our habitations in a healthy condition, and be free from the effects of sewer gas, and the mortality reduced to a state which would not only gladden the hearts of those for whom the work was performed, but the whole community.

Mr. W. Kaye Parry, M.A., C.E., engineer to the Dublin Sanitary Association, read a paper on—

DOMESTIC DRAINAGE IN DUBLIN,

to show that the proper machinery exists in the city to enable the residents to ascertain, for a moderate fee, the sanitary condition of their dwellings, and to afford them disinterested advice and assistance in remedying defects; and, secondly, to suggest some of the practical difficulties which assail the engineer in his endeavour to improve the existing arrangements.

Mr. W. R. Maguire, F.R.M.E. and C.S.I., read a paper on—

PRACTICAL SANITARY LESSONS DERIVED FROM ONE THOUSAND SANITARY INSPECTIONS OF DWELLING HOUSES IN IRELAND.

The paper stated that out of more than one thousand dwelling-houses inspected in Ireland—from noblemen's mansions to six-roomed cottages—only twenty could be certified free from danger to the health of the residents. No selection of these houses was made, they were examined in the order in which they were placed on the books. About fifty of these were tolerably secure though faulty, while twenty only were found free from defect. This, continued the writer, is not a mere statement of opinion, but a record of carefully ascertained facts. Allotting ten persons to each house, we have here over 10,000 persons living under conditions where their lives were continually in need—less danger, and where it is known that many from these causes suffered serious illness, in some cases ending fatally. In the brief time at our disposal we must endeavour to deal practically and usefully with one point of paramount importance in house inspection—the house-drain. The opinion has long been held, and is growing steadily, that we are making very serious mistakes in Dublin, decidedly injurious to the health of the citizens and increasing the

death-rate:—1. By using pipes of 9-inch diameter house-drain, laid across under the streets, connecting houses with the public sewers. 2. By laying the soil without cement-concrete foundation, and they are liable to sink. 3. By not imperviousing the joints. 4. By leading them into direct under the scullery instead of invariably them across under the open area. 5. By not the use of approved interceptor traps to exclude sewer air. The 9-inch diameter drain pipe Dublin are 50 per cent. too large in diameter at their purpose of conveying drainage rapidly houses into the public sewer. It is very important the proper size of house-drains should be adopted great city. Dublin city, exclusive of suburbs more than 25,000 houses in about 130 miles with a population over 250,000. Taking 7 yds feet, of drain under Section 1 as a fair average house, we have 100 miles of drain laid across our ways from houses to sewers under the control of sanitary authority. The length of private house-drains, beside, under, and around houses, extend hundred miles more, but at present we are on with the section under the sole control of the authority. Now, the internal surface area of miles of drain is more or less foul, and is constant off exhalations to the air in the drain; the present this internal surface area of 9-inch to 6-inch is $2\frac{1}{2}$ to $1\frac{1}{2}$, i.e. the 100 miles of 9-inch drain now our streets and connected with our house 1,188,000 square feet of foul surface area compared with 792,000 square feet, the surface of 6-inch drain, an absolutely unnecessary nearly 400,000 square feet of foul surface drains. An estimate of items will show the saving in cost to the citizens, if the more suitable diameter drains had been used, would be a capital round numbers of at least 25,000*l.*, and a saving in money may be effected in future if 6-inch are adopted, besides the saving to life and the importance of forming a hard unyielding foundation drain should never be forgotten. The law or the authority should require all drains to be brought open areas in front of houses, and should forbid drain connection under any vaults having direct access to the houses. That interceptor traps are on the line of drain at some point before they house is held by sanitary engineers, and now admitted. The health of Dublin would be improved if the sanitary authority undertook a examination and test of every house-drain, and their universal reform. There should be an official inspection of the internal fittings of every Turning now to Section 2: the private householder solely under the control of the householder; the classes, drains inside the house walls and drains the house walls. If it is possible to place drains the walls, we are all agreed that they should be even at all considerable trouble and expense. The extreme importance of sound work in drain fittings, does it not seem the most extreme folly to such work done at low rates? The health of a depends on the durability as well as on the tightness of each joint and piece of drain. The inspection of a dwelling, when undertaken by an engineer, should be considered by him as a task to be carefully and faithfully carried out for the of the health and the lives of the future residents.

THE CLOSING MEETING.

At the closing meeting of the Congress, S. Rawlinson, the President, expressed the thanks of all owed to the able secretaries who had arranged for the sections. They had also to thank the Local of Dublin for the support and countenance he persistently extended to them.

Dr. Sykes, Mr. W. R. E. Coles, and Mr. Boulnois, C.E., the secretaries of the three sections, then reported to the meeting what had been done in the sections.

The President announced that the Council had accepted an invitation to meet next year at Leicester. He then moved a hearty vote of thanks to the Provost and Senior Fellows of Trinity College, to the Council of the Royal Dublin Society, the Royal College of Surgeons, the King and Queen's College of Physicians, and to the local Sanitary Association. In no place that they had visited had they received more cordial and hearty assistance than in Dublin.

The motion was passed by acclamation.

Dr. Carpenter proposed a vote of thanks to the Lord Mayor, to which his lordship replied.

Mr. R. O'B. Furlong proposed a similar compliment to the President, who briefly acknowledged it, paying at the same time a tribute to the merits, energy, and ability of Mr. Furlong.

Votes of thanks were also passed to the Presidents and secretaries of sections, and to the Press.

LECTURE BY DR. CARPENTER.

DR. CARPENTER, Chairman of the Council of the Sanitary Institute, delivered a lecture on 'EDUCATION BY PROVERB IN SANITARY WORK,' which is published at p. 135. There was a large audience.

THE BANQUET.

On October 1 the Dublin Committee of the Sanitary Institute of Great Britain entertained his Excellency the Lord-Lieutenant of Ireland and members of the Sanitary Congress and others at a banquet in the Shelbourne Hotel. Sir Robert Rawlinson, President of the Sanitary Institute, presided.

The Lord-Lieutenant, in responding to the toast of his health, said: I will venture to say that no more useful science has been found for the people of the United Kingdom than the hygienic or sanitary science which your association represents so worthily to-night. No one, I think, can have visited that very popular place in London—I mean the Health Exhibition—without seeing how very wide indeed is the range which the net of your society sweeps within its meshes. It is almost impossible to find any subject omitted if you go round that interesting and valuable exhibition. You find food and drinks which are good for health, you find models of houses, of their drainage, their fitting-up; and if you go farther you may see the highest works of art, for mental influences as well as physical influences have to do with health. You may see also not only such matters as those to which I refer, but you may see the extravagances which the vanities of men and women have devised in dress. You may see the sad results of the endeavour to get a very slight waist. You may see the extravagant results of the efforts of men to wear extremely narrow pointed boots. There is nothing in fact which a sanitary exhibition may not embrace within its doors. But I shall not attempt to define your work. I know this, that it has a most useful and beneficial effect on all grades of society, from the richest to the poorest. We all know that in every city there are great difficulties to contend with in regard to sanitary arrangements. London has its Thames, and I think no one will deny that Dublin has its Liffey. Since I have known Dublin, when I first came to reside in this country, nearly fourteen years ago, the question of the Liffey has been a very great one. It is still a great one, and I am afraid it is a very difficult one; but if the Corporation and those who have the charge of the sanitary measures of this city, are enabled—and I hope they may be some day enabled—to carry out this great but difficult work, and that through the exertions which they are making for improving the dwellings of the poor, which are very great in this city, you may hope that if the terrible scourge of cholera comes it may not find many victims among the

poor here. Dublin has some great advantages. It is blessed with fine open spaces—given, some of them, and dedicated to the public by the munificence of some of your citizens—large open spaces close to the very centre of the densest population. You have the Phoenix Park also, which is a splendid place for the recreation and health of the people. In these respects you are very fortunate; and in one most important respect you are probably more fortunate than London and many other large places. I allude to the admirable water-supply which you have. Now, I believe that no greater blessing has been conferred on the people of Dublin than the establishment of the Vartry works and the plentiful supply of that beautiful water to all parts of Dublin. These works are always associated with the name of Sir John Gray.

I believe that in Dublin the Corporation has done a great deal by providing baths, by removing the densely-crowded parts of the city, by encouraging the building of better houses for the poor, through the Artisans' Dwellings Act, and in many other ways they have contributed in a very marked way to the improvement of the sanitary condition of the city of Dublin. In other parts of the country much has also been done. Of course in a country which is much poorer than the sister country you cannot expect that local bodies will take up large operations which cost a great deal of money; but since 1874 and 1878 nearly 1,200,000*l.* has been borrowed and expended by local bodies for the improvement of drainage and water-supply, and in the rural districts last year 50,000*l.* has been expended in various sanitary improvements. I cannot forget one important Act passed last year—the Labourers Act. That Act has already been in operation, but not for long. It has only been in operation for about a year, but sixty-nine provisional orders have been applied for by the Local Government Board, and already the building of over 3,000 houses has been sanctioned under it. When we consider how very bad the houses and cottages of the poor in various parts of Ireland are, I think we may look forward to a very great change in their moral character as well as in their sanitary condition if this Act continues to operate beneficially throughout the country.

The Lord Mayor, in responding, said the Municipal Council of Dublin had very many difficulties to contend against. In reference to the purification of the Liffey, it would be in the recollection of Sir Robert Rawlinson that the Corporation were most anxious to accomplish that work, but they found that the tenders sent in ranged from 500,000*l.* up to nearly a million, and as prudent men the Council did not feel themselves warranted in incurring so large an expenditure, particularly as there were other municipalities which would be equal participators in its benefits, but would bear no portion of its cost. He thought the particular circumstances of Dublin would warrant the Government in taking up this question and passing a Bill to amalgamate the townships with the city. So anxious was the Corporation for the carrying out of the purification of the Liffey they had again taken up the question, and had instructed their chief engineer and chief officer of health to report upon the most satisfactory method for accomplishing it.

THE EXHIBITION.

FOR the first time in their annals the Sanitary Institute appear on Irish soil, and Dublin has very properly been selected for its first appearance in the sister kingdom. In no previous year has the Institute been so well accommodated as regards the building in which to hold their display as on the present occasion, for in the premises of the Royal Dublin Society at Ball's Bridge the executive have at their disposal a hall, the counterpart of which could scarcely be met with in any town in the United Kingdom. The only slight drawback is the distance at which it is situate from the centre of the city. The exhibition, however, is of not so comprehensive a character as some of the prior ones have been. There are a certain

number of English firms who 'follow' the Sanitary Institute wherever they go, and the majority of these houses are present. But the Exhibition is interesting as introducing us to a variety of native-made productions in the shape of clothing, &c. Taking the initiative from the great show at South Kensington, the Dublin newspapers have dubbed the display the 'Health' Exhibition, and with the desire that evidently exists amongst the Dublin authorities for the improvement of the hygienic features of their city, the members of the 'fourth' estate are justified in thus changing the usual appellation. That the authorities are taking great interest in the visit of the Sanitary Institute is beyond doubt, and it is to be hoped that circumstances will induce this useful body to cross the Irish Channel again in future years. The Exhibition was formally opened by the Lord Mayor of Dublin on Sept. 30. One 'new departure' on the part of the executive of the Institute is worthy of note, and which, it is stated, is intended to be carried out on future occasions. This is the fact of the principal portion of the awards being made known on the opening day. For a week previous to the opening the gentlemen who were selected as judges were actively engaged in prosecuting their duties, and the announcement of the prizes at this early stage of the proceedings will be gratifying to the successful exhibitors, as well as a guide to the public and intending purchasers. Mr. Box, the Curator of the Institute must have found his task this year a heavier one than usual, seeing that he had been engaged at the 'Healtheries' until within a very short time of the opening, yet everything in his department was as forward as could be desired. Subjoined will be found a description of the principal exhibits. The exhibition will remain open until the 18th inst.

Messrs. Maguire & Son, of 6, 7, & 8, South Frederick Street, and 10 Dawson Street, Dublin, contribute a display which, for completeness, variety, and strict adherence to sanitary principles and true economy, is not approached by any other exhibit or combination of exhibits in the building; nor is it excelled, if equalled, by any single exhibit at the Health Exhibition at South Kensington. But for Mr. R. W. Maguire, the head of the firm, by whose indefatigable energy this collection has assumed such proportions, the Exhibition would certainly not have been so satisfactory as it is, for as a member of the Local Committee he has rendered yeoman's service. In his own exhibit the arrangement of the drains, for various sized houses and buildings, fitted complete with the most approved ventilators, traps, inspection chambers, &c., is worthy of careful attention. Messrs. Maguire have taken out a patent for jointing drain-pipes as shown

ing, a sort of cradle is provided in which the joint rests. This has the effect: 1st. Of holding the pipe and socket concentric, so that a much more perfect and durable cement joint can be made than by any other system, the joint being equally spaced all round, without the use of wood wedges, so often used by drain layers, which wedges rot away in time, leaving a hole under the socket for leakage of sewage. 2nd. It enables the joint to be got at all round, as it holds the pipes steady and even, instead of lying loosely on the ground. 3rd. It enables a second and independent cement joint to be made on the lower half of the socket where the sewage runs by pouring in liquid cement round the first joint after it has properly set fast, making a perfectly sound, staunch joint, independent of the workman's care and open to the inspection of all concerned. About this portion of the stand and in connection with the above are fitted lavatories, water-closets, &c., complete with cisterns and flushing tanks. They include a variety of designs and qualities to suit the humblest as well as the most expensive requirements, and though differing from one another in some points, are all nevertheless of approved principle. Maguire's Patent Flushing Tank, for the periodical cleansing of drains, calls for especial remark. It is well known that the small amount of water used in closets is not sufficient, or the outlet-pipe from a bath not large enough, to effect a thorough flush of the drains, and it is to obviate these defects that the tank sketched below is introduced. A glance will at once make clear the action. The rain water or bath water, or both, accumulate in tank until the water overflows into balance cistern and weighs it down, opening the large full-bore valve at bottom of tank and discharging the contents with great force through the drains. The water in balance-tank flows back by means of the syphon into the large tank and closes valve for storage again. Being automatic, no attention or care is required, no waste of water occurs, and no expense incurred beyond first cost of apparatus, and yet the house-drains will be kept perfectly clean and thoroughly flushed every day throughout the year, with water that would otherwise dribble away in small quantities. From these, the fundamental appurtenances of every healthy dwelling, the visitor comes to the kitchen. This compartment is fitted up with a close fire self-stove, cooking range, of dimensions suitable for a large family and the cooking utensils, which are mostly copper, and other accessories, are of a first class character. The arrangement is very good, the space made the most of, and many hints may be taken from it. Then come divisions arranged respectively as bath-room and drawing and dining-room.

in annexed cut. In this joint it is claimed that by simple means everything that can be desired is secured in a drain at but slight increase of cost. As will be seen from the draw-

The former contains one of the combination douche, shower, and plunge baths, and the fittings usually in such an apartment of a well-found establishment.

The other apartments are notable as containing the most recent form of stove-grate, ventilators for ingress of fresh

Mr. Thomas Twyford, Hanley, Staffordshire, the patentee of the now universally used 'National and

and egress of vitiated air, and sanitary washable wall-hangings and non-arsenical wall-papers. They are also fitted complete with furniture and ornaments.

Messrs. Maguire & Son are also manufacturers of Dr. Scott's Self-regulating Hot-air Disinfecting Chambers, which they are showing in another portion of the building. This apparatus is pretty well known, having been awarded the Diploma of Merit at the Medical and Sanitary Exhibition of 1881, since when it has been taken up by the War Department, and by many hospitals and municipal authorities in the United Kingdom and abroad. It is very economical to use, burning but a minimum of fuel, which may be either coal or gas. It is constructed of patented improved composite non-conducting material, with non-conducting door, and contains shelves, galvanised iron safety-carrying case, with wicker linings for clothing, inspection valves, and patent automatic safety-valve to regulate heat to any temperature at will. An apparatus for producing steam for moist heat can also be had with it if desired.

Messrs. Doulton & Co. figure as prominently here as they do at the Healtheries, and though their exhibit is of course on a smaller scale, it is quite as representative, being arranged with the utmost completeness, and at the same time allowing everything to be seen and examined with the greatest facility. All Messrs. Doulton's latest improvements, as shown at South Kensington, and including those recently illustrated and described in detail in the pages of the 'EXHIBITION SUPPLEMENT' of the SANITARY RECORD are exhibited at Dublin; the water-closets, urinals, water-waste preventers, flushing tanks, ventilating syphon traps and similar apparatus being in action. Having so lately commented on the valuable points in these appliances, it is merely necessary to note that all the various articles present their usual merits, and if sanitary reform in Dublin and other parts of Ireland is not speedily brought about it will not be through any fault of Messrs. Doulton & Co. in not showing the simplest and most effective sanitary appliances and means for hygienic conditions.

'Crown' closets, sends specimens of these in various qualities, and also a new design known as the 'Unitas' of which a sketch is appended. Each of them is in action and fitted with a flushing cistern for the purpose of practically demonstrating their several advantages. The salient features of the 'Unitas' are that, unlike other w.c. basins

it is not inclosed in woodwork, nor does it require any wood fittings beyond a movable hinged seat supported on brackets. This arrangement prevents accumulations of dust or offensive matter, and by simply raising the seat transforms it into a slop closet or urinal. The flushing-pipe from cistern is easy of access for inspection, and all other joints and connections being in sight, any leakage or other defect can be easily detected. The outside of the basin and trap is of an ornate and pleasing character. Mr. Twyford is a large manufacturer of lavatory-basins and other sanitary ware, and the collection he has sent of the former stands is pre-eminent for excellence of design and finish. Some are shown fitted in handsome cabinet work with connections for hot and cold water complete, while others are ready for fixing or fitting in frames to suit the purchaser's fancy.

Mr. T. G. Messenger, Park Road, Loughborough, exhibits a Syphon Water-Waste Preventer, constructed on rather different principles to the majority of these appa-

ratus. The distinctive feature is that the flow ceases when the handle is released. No valves are used for the discharge of water, and it is claimed that the result is exactly the same as a cistern constructed on the alternating principle.

Earth-closets are well represented by two good makers, each possessing peculiar points of their own. Mr. R. R. Heap, of Greenheys, Manchester, occupies one stand; the British Sanitary Company, Bothwell Street, Glasgow, another. Our first illustration (fig. 1) is a sectional view of the principle that may be said to be common to all, and

FIG. 1.

FIG. 2.

consists of an earth reservoir for storage, a tank that corresponds to the basin of an old w.c., and the seat, which is so arranged that by sitting upon it it is depressed, but on rising, and in connection with two levers on which it rests, a charge of earth is distributed over the excreta. Mr. Heap manufactures a variety of different forms and qualities, but this, which is known as the seat-action, is the most simple and effective; for, being entirely automatic, no one can use the closet without the distribution of earth taking place.

Our next engraving (fig. 2) shows a very simple form, and only requires the tank to make it complete. It is made of ordinary deal, and can be supplied at a very low price. A portion of the apparatus, only to be seen with Mr. Heap's earth-closets, and recently patented by him, is called a 'separator,' and is calculated to obviate an objection hitherto urged, and in other respects to prove a benefit. This consists of an enamelled trough, fixed in the front part with a grating at bottom, and the urine, instead of passing into the 'collector,' or tank, as it has hitherto done, is by this arrangement diverted, and is carried by means of a pipe into another channel, where it may be collected for after distribution. With this addition the earth-closet becomes one of the most complete media possible for the disposal of human excreta, reducing inconvenience to the narrowest limits.

The other illustration appended shows the working of The British Sanitary Company's Patent Self-acting Earth

Closet, which has been described on previous occasions in the SANITARY RECORD. Its chief feature of difference

from others consists in its being fitted with a perforated shovel or scoop D, which by the seat action is brought quickly forward and spreads the earth more uniformly over the excreta than is effected by the ordinary process. It is made in all qualities, specimens of each being shown. Both the above firms have again been awarded the starred certificate of the Institute.

The Hygienic and Sanitary Engineering Company, Charing Cross and Brighton, are showing Bostel's Excelsior Closets in action, notably their No. 3, which contains recent improvements on the original design. These consist of an arrangement whereby a larger quantity of water remains in the basin or receiver, and the flush of water is delivered at the bottom of the basin and not as hitherto on the top, so that the contents are washed away more quickly and more effectually.

Messrs. J. & M. Craig, Kilmarnock, N.B., and the Bourtnehill Company, Dreggorn, Ayrshire, both contribute good assortments of sanitary stoneware, the former consisting chiefly of drain-pipes, traps, &c., and the latter of glazed sinks, washing up troughs, &c.

Antiseptics and Disinfectants are well represented, the most important exhibits being those of Messrs. Jeyes' Sanitary Compounds Company, Cannon Street, E.C.; Mr. Eugene Rimmel; Messrs. Mackey, Mackey, & Co., Fleet Street, E.C.; Messrs. F. C. Calvert & Co., Manchester; and Mr. J. Wheeler, Ilfracombe. Messrs. Jeyes have sent a very complete and well-arranged collection of their valuable and varied preparations, and have again received the award of the Institute. Mr. J. Wheeler has also received an award for his Pixene, one of the most rational disinfectants that have yet been introduced, and one that is coming extensively into use. His Pixene Soap is also very useful, and, though a thorough antiseptic, may be used without the least detriment to the most tender skin.

Mr. E. Rimmel's Transparent Coal Tar Soap possesses similar qualities, combining the purifying properties of tar with the emollient action of a perfect skin soap. His Aromatic Ozoniser, or Natural Air Purifier, as well as a variety of favourite Toilet Waters, are also exhibited.

Messrs. Burroughs, Wellcome, & Co., Holborn Viaduct, E.C., make a very compact and well-assorted display in the sections devoted to Hospital and Sick-room Appliances, Foods, and Dietetics; their stand being replete with samples of the varied pre-eminent preparations with which their name is so well associated, as well as many recent improvements very interesting to the profession. 'Extractum Pancreatis' is one of their latest introductions, and possessing, as it does, very powerful properties for peptonising milk and other foods for the sick, is well worthy of consideration. The jurors have now awarded to it the prize medal of the Institute.

In cooking apparatus the Wilson Engineering Company, of 227 High Holborn, figure the most prominently. They have in previous years received the starred certificates of the Sanitary Institute; and the fact of their again upon this occasion being awarded the same, testifies to the value of the appliances. The illustration represents one of the ranges in connection with which the company have

introduced a further improvement, that, though not relating to its cooking capabilities, is well worthy of note. With the above sketch before them it is scarcely

to remind readers that the Wilson ranges to the class known as self-setting, and that arrangement of the flues is such that all the heat before the products of combustion pass into the . Nevertheless, a considerable amount of heat its way into the chimney, and it is not expected stove could be constructed to prevent this. The therefore fixes a wrought iron tube in the chimney, of which is bent and passed through the wall in the outside fresh air, which, from the heat in ney, is soon warmed and conveyed through proper to warm the apartments or passages in other the building.

Musgrave & Co., Belfast, and New Bond V., contribute an assortment of their famous Slow ion Stoves. A sketch of one is subjoined, but, a No. 13 of the 'EXHIBITION SUPPLEMENT' their valuable qualities, it will suffice now ion that the latest improvement the firm ade is known as the new Double Chamber

rently attracting as much attention and exciting as much interest in the sister isle as they do in other parts of the United Kingdom.

The articles made by Messrs. Buchan, Kite, and Ellison may be said to deal directly with the subject of ventilation ; in contradistinction to those of Messrs. Adams and Leggott, which deal with it more indirectly, though no less efficiently. The former consist of inlets for fresh air to be inserted in the walls of rooms or public buildings, and cowls for fixing on the roof to carry off the vitiated air, while the latter are designed to render the opening of heavy sashes or fanlights a matter of simplicity and ease, and at the same time prevent the possibility of these or our ordinary room windows being interfered with by thieves or others from the outside. They therefore provide a means of keeping up a constant supply of fresh air to apartments, warehouses, &c., with perfect safety, when not occupied.

It will be remembered that the inlet ventilators of Mr. Ellison are constructed on the conical principle, the

Combustion Stove, with patent dust preventer, and main features of it are great heating power, cleanliness, and safety. The arrangement is ingenious and complete, and provides for a constant stream of warmed fresh air in the apartment.

appliances appertaining to ventilation those contributed by Mr. W. P. Buchan, Glasgow; Messrs. Kite & alston Street, N.W., Mr. R. Adams, Borough, London; Mr. J. Ellison, Leeds; Messrs. W. & R. Bradford, Yorkshire; and Wenham's Patent Gas company, 12 Rathbone Place, W., London, are noteworthy.

most four mentioned are so well known to the staff of this journal, and to the public generally, known as standard articles, that to detail their merits is quite unnecessary. It will therefore mention the fact of their being here, and appa-

erture being smallest at the outside end, and gradually increasing in diameter inwards; the result is that, however strong the wind may be, it will enter the apartment imperceptibly, and without draught. This principle has lately been adapted to tubular ventilators, and are known as Ellison's Patent Expanding Ventilating Tubes, their practical value being very much increased by the low price at which they are offered. This consideration of price in reference to a really efficient apparatus has also brought Stevens' Patent Cowls, also made by Mr. Ellison, prominently forward. Mr. Stevens is able to supply a 10-inch cone ventilator with 4-inch shaft for 13s., and a 24-inch cone with 12-inch shaft and square base for 2l. 18s. 6d.

The 'Wenham' Patent Lamp provides light and ventilation at the same time. It burns gas on the regenerative principle, giving a powerful and shadowless light for a minimum consumption of gas. A perforated ceiling plate

communicating with a shaft carries off the vitiated air from the room. An illustration and further details of this invention will be given in another issue.

Messrs. J. L. Bacon & Co., 34 Upper Gloucester Place, exhibit their system of Heating and Ventilating, one of the salient features of which is the peculiar make of pipe used for the hot water coils. It was originally introduced by this firm, and our illustration is a full-sized sketch of it with a joint. In this apparatus the ordinary boiler is replaced by a series of tubes bent in tiers one over the other and disposed in the interior of a furnace, the temperature of which tubes steadily increases throughout their length; a considerable economy of fuel can be secured by careful disposition of the tubes and construction of the furnace; for it is manifest that the temperature of the escaping smoke need only be slightly in excess of that of the return pipes or about 190°F .; whereas in the ordinary boiler where perfectly free circulation is possible,

phenomena of ebullition are avoided, and the heating surfaces can, by regulating the valve accordingly, be raised to very high temperatures without the formation of steam. The system is therefore peculiarly applicable for drying closets and stoves for manufacturing purposes where great heat is required, and where the ordinary system of hot-air flues is inexpedient, both on account of danger from fire and damage from noxious vapours. But since laws of hygiene forbid the employment of overheated metal surfaces for the ordinary purposes of heating, the apparatus is in such cases constructed so that the surfaces cannot exceed a mean temperature of 237°F ., with the result, that while in every way obedient to those laws, the greatest possible effect is obtained from the tubes, and one considerably in excess of that obtained from other systems of circulating apparatus.

Messrs. Bacon have special systems of ventilation which are applicable to buildings of various kinds, and they are

and the temperature of the water is practically the same throughout, the heat of the flow pipe governs that of the chimney. The result of this is economy of fuel and rapidity of heating. Amongst the other advantages possessed by this system the following are also worth noting:—

Ease of Application.—In consequence of the superior quality and small diameter of the tubes, and the facility with which they can be bent, the apparatus is equally applicable to old or new constructions, for it can be introduced without disturbance to existing arrangements, and does not necessarily entail the construction of trenches or channels for connection mains, an inconvenience in other systems often debarring their employment. The expenses, therefore, accessory to its introduction are very trifling, and as the circulation does not depend on the tubes being laid at a slope, the apparatus is not unsightly.

Simplicity of Management.—The action of the apparatus being that of the simple circulation of liquid, induced by lighting the furnace fire, all the difficulties arising from condensation, air stoppage, and the consequent necessity for attention to valves and air-cocks, are avoided. The management is, indeed, so simple that it can be left to the care of any ordinary house servant.

Durability.—The whole apparatus, when erected, is tested by hydraulic means to a pressure of 130 atmospheres, and since the valve is regulated to blow off at six atmospheres, it is manifest that leaks are of rare occurrence. Further, in consequence of the unusual character of the material employed, viz., *corrugated iron*, breakage is impossible, even in the event of the greatest violence. Hence, the cost of maintenance, often such a heavy item, and so difficult to estimate in the case of other systems, such as steam, cast-iron hot-water pipe, or hot-air apparatus, is in the case of this system practically nil: instances have been known where apparatuses have been in use over fifteen years without entailing the least expense for repair. **Heating Capacity.**—The apparatus working under a valve, the

prepared to make schemes suitable for any building either old or new. In large buildings a fan worked by a gas engine is generally used to extract the vitiated air, the fresh air being warmed before entering the rooms by passing over the hot pipes. This system has been largely adopted on the continent with great success.

Messrs. Choriton & Dugdale, of Manchester, make a first-rate display with every variety of their 'Excelsior' Spring Mattress, Adjustable Invalid Couches and Chairs. The engraving indicates one of their newest introductions

of the latter articles. A brass rod on the right hand side of the sitter with an endless screw at its lower end working on a cogged wheel of gun metal, enables him to alter the position of the back, without rising from his seat, to any inclination he desires. It also forms a most luxurious reclining or smoking chair.

Messrs. Billington Brothers also show their 'Liverpool' Spring Mattress as illustrated in the accompanying sketch. The special features of the appliances manufactured by this firm have been pointed out on other occasions in the

SANITARY RECORD; their present exhibit includes a Hospital Bed, which is very compact and comfort-

le; and an Invalid's Bed with head-rest, which can be adjusted to the greatest nicety; a Portable Bed and Liverpool Spring Mattress and a simple and inexpensive Adjustable Invalid's Chair.

Messrs. Bradford & Co., Crescent Ironworks, Manchester, and High Holborn, W.C., are entered in two classes, viz., Laundry Machinery and Appliances, and for Disinfecting apparatus. The former comprises their well-known Wash, Wringing, and Mangling Machines in a variety of sizes, and a model of a 'Radial' Drying Closet. This is a brick structure built up to dado height, with bricks, and above the dado with ordinary brick. One side is fitted with a powerful but economical fan, known as the 'Reversible,' from the fact that the upper and lower halves of it are made in duplicate so that when, after several years' wear, the upper part is burnt or cracked, it is simply necessary to turn it over the stove to be again for all practical purposes as good as new. A large number of flat-irons can be heated on the stove; and it gives off into the closet a very high temperature with proper ventilation, which it is claimed will dry the heaviest linen in from fifteen to thirty minutes, the moisture being carried away most effectually by a special ventilating shaft gathered into the main flue. A holding the linen a 'Radial' upright horse is fixed, having some twenty or thirty arms, according to the height of the closet, upon which the linen is placed, the arms upon each arm hanging clear of every other arm. Mr. Maignen, of Great Tower Street, E.C., is exhibiting his Filtre Rapide, and, judging from the crowd con-

gathering the filter, as represented in the woodcuts, the necessity of securing pure water is fully recognised. It

Setting

Cleansing.

has been pointed out on previous occasions in the SANITARY RECORD and recently in the HEALTH EXHIBITION SUPPLEMENT that a filter to be really useful and to fulfil the purpose for which it is intended, must be periodically cleansed, and the method of cleansing such that any inexperienced person can accomplish with facility. Visitors can see that Maignen's Filtre Rapide meets these requirements to the fullest extent.

Messrs. Robinson & Bamsdale send a case of their 'Strawfena' Cigarettes, the hygienic peculiarities of which have already been pointed out in the SANITARY RECORD.

Messrs. Groom & Co., Liquorpond Street, E.C., contribute a very commendable assortment of sanitary, domestic labour-saving and improved culinary appliances. They include the Well and Dry Platform Sponge Bath, the Registered Milk Saucepan, the Registered Hot Water Plate, Bacon Dish and Toaster, and Bowers' Patent Potato Steamer. All these have recently been referred to in detail in our report of Messrs. Groom's exhibit at South Kensington in the EXHIBITION SUPPLEMENT; they likewise excite much interest amongst the visitors at Dublin, and the Potato Steamer has characteristically received the award of the Institute.

The stand of Mr. W. Rothwell, 16 Market Street, Bolton, Lancashire, attracts much notice and great approval. Knitting machines in several sizes, constructed on principles only recently perfected by the patentee and exhibitor, and different and superior to any other of their kind in existence, are there to be seen. After careful examination and trial, the jurors have awarded them the Silver Medal of the Institute, and the attention of our readers is drawn to them because they are specially adapted for workhouses, industrial, and other public institutions, to take the place of manual labour, inasmuch as the most inexperienced operator may learn how to use them in three or four days, and in a few weeks become quite expert in knitting hose, mittens, jerseys, and so forth. Machines of a similar character are also being exhibited by other firms, some of which have already been described in these pages.

The Donegal Industrial Committee are exhibiting a case of Hand-knitted Socks and Stockings in silk and wool, and some very beautiful specimens of Embroidery, all the work of the peasants of the north-west coast of Donegal. The former are made up of the most artistic colours, though dyed solely with vegetable dyes, the hygienic properties of which have so satisfied the judges that they have awarded to the Committee a prize medal. Undyed and Vegetable-dyed Homespun Woollen Fabrics, made in the same district, are also shown, and the exhibit generally is exciting a very considerable amount of favourable interest amongst the visitors.

gathering congregated around his stand, and the interest every-where evinces in the various processes of 'setting' and

The following exhibits of local firms are well worthy of note in relation to the hygienic character of the Exhibition:—

Mr. Wm. Baird, 27 Lower Abbey Street, shows some handsome and well-fitted lavatories and a combination bath, similar to those manufactured by Conolly & Co., recently described in the *SANITARY RECORD*. Mr. Baird also makes a special feature of hydraulic drains, turbine wheels, pumps, &c., and sends some first-rate work of this class. Mr. J. L. Smallman, 23 Temple Lane, has some good syphon cisterns, with arrangements for working them by the ordinary lever and by door action.

Mr. C. Cadle, 39 Wellington Quay, shows hydraulic machinery, including Leffel's Improved Patent Double Turbine Water Wheel. The one shown is 20 inches in diameter, and fitted with wrought-iron buckets and adjustable steel gates. It is suitable either for pumping or ventilating, and on a fall of 20 feet will give 22 horse-power.

Messrs. T. Dockrell, Sons, & Co., of South Great Georges Street, and Mr. William Martin, 18 Stephens Green, North, send admirable collections of artistic decorations, including stained-glass panels, art tiles, and wall-papers. They are of the newest designs, and the latter, being manufactured without the use of arsenical pigments, are thoroughly innocuous.

Messrs. F. R. Scott & Co., 32 & 33 Upper Abbey Street, make a special feature of Solid Oak Parquet Flooring, and for which they have received an award; they also show art furniture of first-rate design and finish.

Messrs. T. Pearson & Co., 11 Ship Street, are manufacturers of Woven Wire Spring Mattresses, which they show in different sizes, fitted complete to bedsteads, so that a fair opinion of their value can be formed.

Mr. Walter Fleming, 47 Dawson Street, also shows a good assortment of bedsteads fitted with spring mattresses.

Mr. John Kehol, 40 South Richmond Street, exhibits a spring mattress stuffed on both sides, so that it can be reversed, and it has perforations to admit a current of air for ventilation.

Mr. Arthur Webb shows Waterproof and Hygienic Boots, &c., and Messrs. F. Smyth & Son and Mr. J. Morgan show respectively, umbrellas, hats, pith helmets, &c., of Irish manufacture.

Mr. F. Leveson G. Gunn, of Rochdale, Rathgar, has a wire screen, fitted in front of an aperture, which represents an ashpit through which the dust passes, leaving the cinders in a sort of basket, from whence they are easily gathered to be again utilised for fuel.

The Glen Mills Co., 37 Exchequer Street, contribute to the general interest with specimens of fine flour, wheat, and other meals, all manufactured at their mills; their exhibit also includes the well-known American Breakfast Cereals, the chief British depôt for which is at 44 Great Tower Street, London, E.C.

Mr. F. Tellwright, 47 Grafton Street, shows filters, and Mr. S. Boyd, 46 Mary Street, an assortment of disinfectants, including chlorate of lime, carbolic preparations, &c. The latter has an interesting case containing models of ingredients used in the manufacture of dynamite.

THE AWARDS.

The following is a list of awards made at the Congress of the Sanitary Institute:—

MEDALS AND CERTIFICATES.

*Bradford & Co., London, for washing machines; *British Sanitary Company, Glasgow, for self-acting earth-closets; Burroughs, Wellcome, & Co., London, for powders for peptonising milk; *J. C. Calvert & Co., Manchester, for carbolic acid and its preparations; *Chorlton & Dugdale, Manchester, for Excelsior spring mattress, for 'swing' woven wire mattress; J. & M. Craig, Kilmarnock, for white enamelled fire-clay for sinks; Doulton & Co., London, for art pottery; *Doulton & Co., London, for venti-

lating tile store; *Doulton & Co., London, for anti-percussion high-pressure valves; *J. E. Ellison, Leeds, for conical ventilators; *R. R. Heap, Manchester, for dry earth or ashes closet; Maguire & Son, Dublin, for their exhibit of sanitary and domestic appliances; *P. H. Maigen, London, for filtre rapide; Mackey, Mackey & Co., London, for chemical substances used in disinfection; Musgrave & Co., Belfast, for slow-combustion stoves; Pim Brothers, Dublin, for exhibit of furniture; *J. L. Smallman, Dublin, for Stott's mercury gas governor; Shanks & Co., Glasgow, for syphon action water-waste preventer; *Wilson Engineering Company, London, for their Wilson cooking range; D. J. Wright & Co., Birmingham, for Eureka gas cooking stove, and the silver medal of the Exeter Gas Company.—[A starred certificate signifies that the recipient would have received a medal but for the fact that one had been awarded to them on a previous occasion.]

CERTIFICATES.

Robert Adams, London, for the Norton door spring; same, for adjustable pivot for fanlight; Baird, Thompson, & Co., Dublin, for butler's sink, lined with block tin; same, for white enamelled fire-clay sink; same, for bath, with shower, douche, and spray fittings combined; same, for lavatory, with shampooing apparatus; Thos. Baird & Co., Glasgow, for Watt's asphyxiator for testing drains with smoke; Billington Brothers, Liverpool, for portable bed, with Liverpool spring mattress; Bourtreehill Coal Company, Dregghorn, Ayrshire, for stoneware drain-pipes; same, for white enamelled fire-clay sinks; Burroughs, Wellcome, & Co., London, for absorbent cotton and antiseptic sponges; F. C. Calvert & Co., Manchester, for carbolic soap and for soluble cresole; W. Carson & Sons, Dublin, for Willesden waterproof paper canvas; Chorlton & Dugdale, Manchester, for hospital bed fitted with raising appliances; same, for pitch pine lath mattress; same for hospital bed, with new spring mattress; T. Cordingley & Sons, Bradford, for granite concrete pavement; J. M. Craig, Kilmarnock, for Buchanan's disinfecting trap; Doulton & Co., Lambeth, London, for vacuum flushing cistern for closet, with seat action arrangement; same, for cheap glazed stoneware sinks; same, for bath fitting locking apparatus; same, for Lambeth combination water-closet; same, for enamelled ware open channels for manholes; same, for manholes for drains, with connections complete; same, for London-made stoneware pipes; same, for silicon tread for steps; same, for glazed ware mantelpiece, with slow combustion grate; Dublin & Wicklow Manure Company, for alum cake; J. E. Ellison, Leeds, for radiator ventilation; J. W. Elvery & Co., Dublin, for gentlemen's ventilated waterproof overcoats; same, for the Leander lifebelt; W. Fleming, Dublin, for the combination bedstead; Fletcher Brothers, Dublin, for exhibit of tricycles; W. Graham, Dublin, for ventilated hats; Groom & Company, London, for Bower's potato steamer; Jeyes' Sanitary Compound Company, London, for Jeyes' perfect purifier; W. & R. Leggott, Bradford, for opener for fanlights and skylights; Maguire & Son, Dublin, for white enamelled fire-clay sinks; same, for cast-iron drain-pipes coated with Angus Smith's preparation; same, for Marsden tiling for wall decoration; same, for new laundry stove and copper boiler; same, for Scott's self-regulating disinfecting chamber; T. Morgan, Dublin, pith helmet.

CERTIFICATES.

Pennycook, Glasgow, for the system of glazing without putty; Pearson & Co., Dublin, for the institution bed with woven wire mattress; Pim Brothers, Dublin, for the hinged cot; F. R. Scott, & Co., for solid oak parquet flooring; Shanks & Co., Glasgow, for cast-iron bottles, and for porcelain lavatories; Smith, Elder, & Co., London, for sanitary publications; Patrick Short, Dublin, for the rhinoceros hide 'S' boot; Stephenson & Trow, Liverpool, for stygium absorbent antiseptic surgical dressings; T. Hanley, Twyford, for lavatory basins, and for

stop sinks; A. Webb, Dublin, for the 'National' boot for ladies; T. Wheeler, Ilfracombe, for Pixene; W. Wilby, Dublin, for chair belting for machinery; Groom & Co., London, for self-indicating tea or coffee infuser; T. M. Craig, Kilmarnock, for white enamelled bricks; Bourtreehill Coal Company for same; Wright & Co., Birmingham, for ventilating open gas fire; W. Carson & Sons, Dublin, for tortoise slow-combustion stoves; Tyrell Brooke, Dublin, for exhibit of furs; Scott & Co., Dublin, for exhibit of furniture; Boyd, Dublin, for soaps; same, for chemical substances used in disinfection; T. Twyford, Dublin, India-rubber connection for joining lead and earthenware pipes; Harden, Hill, & Co., Birmingham, for gas cooking-stove lined with white tiles.

DEFERRED EXHIBITS.

William Baird, Dublin, turbine-wheels and hydraulic-rum; Bensdorff & Co., London, soluble Dutch cocoa; Bourtreehill Coal Company, washing-tubs; J. L. Bacon & Co., London, heating apparatus; C. Cadle, Dublin, cotton belting; C. Cadle, Dublin, double turbine water-wheel; C. Cadle, Dublin, Blackman a.r.-propeller; W. Carson & Sons, Dublin, anti-corrosive and other paints; J. M. Craig, Kilmarnock, washing-tub; J. M. Craig, Kilmarnock, Shield's flush-out w.c.; J. M. Craig, Kilmarnock, white enamelled fire-clay laundry-trough; Cantrell & Cochrane, Dublin and Belfast, ginger ale, sparkling Montserrat, and mineral waters; Dublin and Wicklow Manure Company, Dublin, Strype's process for drying blood; F. Dockrell & Sons, Dublin, cheap artistic non-poisonous and washable wall papers; Doulton & Co., London, automatic flushing-tanks; same, waste-preventing valve for water-closets; same, automatic flusher for urinals; same, jointed pipes; same, grease interceptors—since awarded a medal; the Glen Mills Company, Dublin, self-raising flour; Maurice Gandy, London, cotton machine belting; J. Hotblack & Sons, Norwich, the health boot; Holohan & Sons, Dublin, mineral waters; Denny Lane, Cork, Silver-spring rice starch; Maguire & Son, Dublin, safety joint drains; Maguire & Son, Dublin, sanitary reform urinals; Maguire & Son, Dublin, white enamelled fire-clay laundry-trough; Maguire & Son, Dublin, white enamelled fire-clay washing tubs; Maguire & Son, Dublin, sanitary reform universal water-closet; M'Dougal & Gunn, Glasgow, Lavage-boon and soaps; P. & A. Maignen, London, process of softening water; Pim Brothers, Dublin, sewing machines; Ross & Co., Belfast, ginger ale, non-alcoholic drinks, and mineral waters; E. Rimmel, London, transparent coal-tar soap; W. Rothwell, Bolton, knitting machines; A. & R. Scott, London and Midlothian, oat flour; Shanks & Co., Dublin, mineral waters; Wenham's Patent Gas Lamps Company, London, regenerative gas-burner; Wilson Engineering Company, London, system of utilising the waste heat from cooking range; T. Edmundson & Co., Dublin, electric lighting; Doulton & Co., London, Maignen's carbon filters.

ANTIMONY IN CLOTHING. The *Centralblatt für Textil Industrie* records the fact that antimony is to be found in cotton yarn which has been dyed with aniline colours, and remarks that unless great care has been taken in the cleansing of the yarn, it is possible for such a quantity to remain as to be injurious to the skin. Experiments made on different classes of yarn produced results varying according to the nature of the dyeing substance. The samples in which hot water acted as a dissolvent showed only a small proportion of antimony, the highest proportion being found 0.014 per cent. The proportions of antimony which were soluble in muriatic acid varied from 0.036 to 0.31 per cent. of the weight of the yarn. Of course, practically speaking, only the portion soluble in water comes under consideration, but as a pair of long stockings weighs about 2 to 2½ ounces, the antimony would represent an appreciable though minute quantity, the effect of which is a question, it is remarked, for medical experts to decide.

SOCIAL SCIENCE CONGRESS.

At the twenty-eighth meeting, held at Birmingham from the 17th to the 24th ult., the general president was the Right Hon. G. J. Shaw-Lefevre, who delivered the Presidential Address. In the Health Section the president was Dr. Norman Chevers, who delivered the inaugural address, which dealt with the inefficiency of sanitary administration in England, and its probable improvement by the appointment of a Minister of Health.

One of the special questions in this section was

WHAT ARE THE BEST MEANS, LEGISLATIVE OR OTHER, OF SECURING THOSE IMPROVEMENTS IN THE DWELLINGS OF THE POOR WHICH ARE ESSENTIAL TO THE WELFARE OF THE COMMUNITY?

to which Mr. John Hamer, hon. secretary to the Mansion House Council on the dwellings of the people, furnished the following elaborate reply:—

Among 'other' means he placed in the foremost rank associations of men and women whose object is, by personal visitation of and familiar intercourse with the masses, to arouse such feelings of sympathy, hope, and courage as shall educate the people themselves to a proper degree of independence, love of order, and decency. The condition of thousands of our fellow subjects is what it is because they do not know what it is. Many splendid efforts have been made in this direction. They are grand in themselves, but they are like drops in the ocean. These efforts must be multiplied a thousandfold. The Mansion House Council, appointed Dec. 11, 1883, seek to enforce the laws. They addressed themselves to the formation of local sanitary aid committees. The metropolitan area has been divided into convenient workable districts, and thirty-three committees, of from twelve to twenty members each, have been set to work. Papers setting forth sanitary defects are freely circulated from house to house and complaints invited. No distribution of charity is made. The general duties of local committees are to receive complaints regarding sanitary defects and to deal with them. The Council has been most encouraging, but they are still in want of workers, especially of such as can and will work in the East End and in the southern districts. Several hundreds of ladies and gentlemen have been brought into personal contact with the poor in their daily life. The Council believe that they are in a fair way to be able seriously to grapple with this great social problem. The Council is gradually becoming a means of intercommunication between persons desirous of purchasing bad property, with a view to converting it into habitable dwellings, and owners willing to dispose of the same. Many vestries and other local authorities, but not all, have, through the action of the Council and its local committees, been aroused to a sense of their responsibilities. The rapid growth within the last quarter of a century of the temperance movement in its various forms has worked wonders in the reformation of the habits of the people, and in the restriction of the drink traffic. Still, in the East End recently, house after house was pointed out to Mr. Hamer as taking 50s. to 100s. a week for beer and spirits from the wage earners whose homes form some of the worst slums in that neighbourhood. The preservation of open spaces for recreation, and the opening of coffee palaces have done great service. The building of better houses for the people, when undertaken and managed on commercial principles, is strongly to be commended—but the results in London have not, so far, been all that could be desired. The houses are provided, but the right class of people are not living in them. The rents are too high for the labouring class. The machinery at present at work for enforcing the laws of sanitation is terribly deficient. For 4,000,000 people, living in 500,000 houses, the wealthy metropolis generously provides fifty medical officers of health, who do not average a couple of inspectors each to assist them. That is to say, each sanitary official has to look after the

health of 26,000 persons. The Local Government Board issued a circular urging the district authorities to put in force the regulations as to houses let out in lodgings. Out of the thirty-nine governing bodies in London how many have complied with this suggestion? Not half a dozen. The Royal Commission sent out blank forms asking their aid in the collection of statistics vital to the efficiency of their inquiry, and the responses have been practically nil. District surveyors when they bring an action against any one for infringing the Building Acts do so at the risk of having to pay the costs of the action out of their own pockets if they fail. Twenty-two thousand persons have been compelled to leave their insanitary homes under the power of the Industrial Dwellings Act. Accommodation has been provided for 14,000 of these. Where, meanwhile, are the 8,000? Nuisances have to be sought out. The power to delay, postpone, and ultimately defeat by sheer procrastination, is one of the worst evils the would-be sanitary reformer has to contend with. The outbreak of infectious disease has to be watched, and the measures taken to prevent its spread. The sanitary authorities exist rather for the removal of nuisances than for the prevention of disease. With regard to disease produced, say, by infected milk, they can do nothing until disease has been produced by its consumption. After a site is covered, houses built, and inhabitants exposed to ill-health or lost their lives, London thinks it well to give to the sanitary authorities power to act. Prevention should be the base of all sanitary regulations. We should adapt our official machinery to our altered circumstances and create a Ministry of Health and Education. The health of the people and the education of the people are so vital to the whole nation that their regulation should be a national, in other words a State, affair.

DISCUSSION.

A prolonged discussion ensued. The operations of the Mansion House Council were almost entirely ignored as being in great measure justified only by the peculiar position of the metropolis, and not called for under municipal administration, which commanded the confidence of the people. The general opinion seemed to be adverse to the erection of dwellings by town councils and local authorities. It was urged that the workmen who traversed London might as well spend the time in going to and from the country, and that to tax the community that a few might live near their work was practically to give a bounty to their employers.

To this the President of the Congress (Mr. Shaw-Lefevre) answered that if it was true, as stated, that in Birmingham the recent inquiry revealed the fact that there were only twelve cases where more than one family dwelt in a room, he could only say that it was a condition of things very different to that of many other large towns. In London there were thousands of such cases, but the case of London, in a sanitary point of view, was more difficult than that of any other town. That was due to many causes. The value of property in the centre of London rendered it almost impossible for workpeople to obtain houses at a cheap rate near their work. There were two kinds of legislation affecting the dwellings of the poor: one, the Torrens Act, which dwelt with individual cases; and the other, Sir R. Cross's Act, which dealt with collections of houses. The Torrens Act could not be improved for the purposes for which it was intended, but both Acts required intelligent local action. If we could get a good authority to carry out these Acts in various localities we should to a great extent solve the difficulty. The Cross Act was more difficult to deal with, and he had himself carried an amending Act in 1882. The original Act enabled local authorities to destroy whole districts of bad houses. In many cases this was the only possible method of dealing with them, but on the condition that we built artisans' dwellings on the sites. The difficulty in such cases was the enormous cost of the land so taken, and he was surprised that the Metropolitan

Board of Works had done so much. Many houses had been removed at a cost of 500*l.* family. The Act of 1882 provided that artisans need only be built upon one-half of leaving the other to be used for commercial purposes. It had been shown by investigation that the people were turned out were not living in the houses they were near their work, but that in many cases they had to traverse the metropolis to go to their work, sometimes in the suburbs. Under those circumstances there did not seem to be any particular necessity for local authority to build the houses on the same land could be procured elsewhere, and perhaps at less work of some, at a cheaper rate. It might be questioned whether the Act might not be further amended in respect, so as to permit freedom of action on the part of the local authority. A serious consideration of compensation to the owner of the premises. The intention of Sir R. Cross's Act that they should be compensated to their full value, and no doubt he thought that that would reduce the cost of the site, but had fallen into the hands of technical men, who were to be very much impressed with the value of land. The conservative ideas of that kind were to be found in the minds of the arbitrators who dealt with the subject. The consequence was that owners obtained compensation amounts which to him appeared preposterous. The question was whether owners who had allowed property to fall into such a bad state and to become a nuisance to the neighbourhood ought to be compensated to the same extent in the ordinary manner. The houses bought and sold for letting in tenements, and on lease had only a few years to run the owner made no repairs, thinking it was not worth while, at the end of the lease the site would be taken. If an owner to be compensated in the ordinary manner or were we to take into consideration that there was a moral obligation on his part to turn out the people who had been living on the premises from time immemorial? If they were taken into account, as he thought they ought to be, compensation to be paid ought to be very much reduced. Then came the question of compensating the middle class. Many of these houses were held by men who took on a lease at a low rent, let them to poor families that way made a large income. The present compensation to such men was that the difference between the rent they paid and the income they received was taken and capitalised, and the result was another sum for compensation. Before the Royal Commission he had ventured to contend that such men ought to be compensated on the basis that if they were business men; they devoted their whole time to business, and they ought to be compensated in the same way as any other persons whose business premises were taken from them. If such a principle were to be applied it would work out a great difference in the sum of compensation; they might also reduce the cost by reducing the rate of interest charged by the State. It was Sir R. Cross's intention that the State should advance a low interest for the purpose of purchasing the sites. An Act of 1879 raised the rates of interest. It was wise to return to Sir R. Cross's original intention of reducing the rate of interest give assistance to the local authorities in that way. The continuance of the state of things in the worst parts of London was to the mismanagement of the local authorities by the state of the law, which did not provide methods of preventing owners misusing their property. In that he believed it to be a legitimate object of the State to contribute towards clearing such rig that could be done in no better way than by a money at low rates of interest. These were the points which the Acts might be amended which enabled the local authorities to put them in force. He was strongly in favour of the local authorities building for themselves; it

etter left to private enterprise. Nothing but mischief would result from the local authorities providing houses for the poor. What they had to do was to put a stop to the mischief which already existed.

Professor Gairdner said that the action taken in Glasgow had been largely beneficial. The population which had been displaced was the better for it. He did not see any principle by which the local authority could step in and become landlords without seriously interfering with the law of supply and demand. The principle upon which the work ought to be done was that of upholding the good and condemning the bad, so that if a man built a house he would be certain that if it did not satisfy the authorities it would have to come down. If that rule were made and rigidly adhered to, it would prevent the monstrous evils which had occurred in many great towns.

Mr. Mark Judge, as a director of one of the largest companies, declared that enterprise was checked by the unfair competition of bodies with trust funds not seeking profitable investment, and thus the commercial solution of the question was retarded.

Mr. H. H. Collins said he had successfully advised manufacturers to take their works into the country, and, of course, the workpeople must follow the works. Thus land in towns might be left to realise its commercial value.

THE BRAIN OF THE SCHOOL CHILD.

In a paper bearing this title Dr. Francis Warner drew attention to the nervous, irritable children—children who were irregular in attendance on account of headaches, recurrent chorea, occasional fits; habitual truants, whose brain defect could be proven; the child so dull that it remained among the infants and learnt nothing. Such children were practically not educated. They were not neglected intentionally, but because they were not known to the school managers; they were not classified, and took their chance with the rest. Now, he believed it was possible to discover such children and pick them out by definite physical signs. Such tendencies ought to be detected early, and pointed out to the educationalist, that he may tend such cases carefully, helping to correct the defects due to brain condition.

The special question—

WHAT IS THE BEST METHOD OF DEALING WITH TOWN SEWAGE, THE PRODUCTS OF HOUSES AND STREET SCAVENGING, AND THE PRODUCTS OF COMBUSTION?

was answered by Mr. T. Pritchard with reference to town sewage. He said that the answer to such a question some fifteen to twenty years ago would have been in favour of irrigation: the experience of the last few years had, however, caused a considerable modification of his opinion as to the best method for adoption, varying according to local circumstances and conditions. The writer called attention to the conflicting opinions of chemists regarding the oxidising properties of rivers for the purification of sewage effluent when discharged into running water many times its volume. One eminent chemist asserted that such water, when well oxygenated, was the most effective in rendering into harmless inorganic salts the polluting organic matter contained in sewage effluent, while other eminent authorities asserted, on the contrary, that zymotic diseases were propagated by organic germs in such water, which were practically indestructible. In the interests of sanitation a hope was expressed that the important question should be speedily determined, more especially as when during epidemics the influence possessed by polluted water promoting the spread of disease was considered. He described the works of the Birmingham, Tame, and Rea District Drainage Board, a system which disposed of the sewage from a population of over half a million, and a system for the town of Wednesbury, of which he was the engineer, the method adopted being one of chemical

precipitation and filtration through land, the precipitated sludge being pressed into cake containing 45 per cent. of moisture by compressed air and Johnson's sludge presser, thus rendering it easy of removal without creating nuisance. On the whole, irrigation was the best means of treating town sewage, inasmuch as both complete purification and utilisation of the sewage may be obtained by this method. But no one particular system for the treatment of town sewage could be adopted for universal use, but the local conditions and circumstances connected with each town must be carefully considered, and a method of sewage disposal prepared in accordance therewith.

Mr. Lawson Tait, F.R.C.S., Chairman of the Health Committee of the Birmingham Corporation, read a paper 'ON THE UTILISATION OF TOWN REFUSE,' which will be found at p. 131.

A discussion followed, in which Mr. Baldwin Latham advocated the utilisation of London sewage, which might be effected on the north side of the river, although the south side was unsuitable; and Mr. W. C. Sillar expressed his conviction that sewage matter might be utilised so as at least to avoid loss, even if no profit were made.

In a paper on 'THE BEST METHOD OF DEALING WITH THE PRODUCTS OF COMBUSTION,' Captain Douglas Galton, F.R.S., referred to the efforts made by the Smoke Abatement Society with this object. But it might be accepted as an axiom that it was not by methods for improving the consumption of crude coal that we should ever arrive at freeing the atmosphere from smoke. To do this effectually we must resort to gas. It was nearly thirty years ago that the late Sir W. Siemens endeavoured to introduce into Birmingham gas for heating purposes, both for manufactories and for houses; but the opposition of the then gas company prevented this grand experiment, and it had been in abeyance ever since. Messrs. Minton in their pottery kilns and others had by the use of gas succeeded in abolishing smoke.

Mr. Noel A. Humphreys read a paper on the question— HOW FAR MAY THE AVERAGE DEATH-RATE OF A POPULATION BE CONSIDERED AN EFFICIENT TEST OF ITS SANITARY CONDITION?

of which the following is an abstract.

In the opening of his paper, Mr. Humphreys urged the public need for some numerical test of sanitary condition, and to the increasing use of the death-rate for this purpose, he refers much of that growth of public interest in health matters which has been the mainspring of recent sanitary progress. In view of this plea for a numerical test, and of the good that has already resulted from the use of the death-rate for this purpose, the inexpediency of its surrender is pointed out, except under one of two conditions; unless its use can be proved to be absolutely mischievous, or unless a better numerical test can be provided in its place. The detractors of death-rates consist in part of those who are only partially acquainted with the true and extreme effect of various disturbing influences of death-rates; while others object to death-rates as tests of sanitary condition because, in the interest of sanitary authorities, they give a limited signification to the term 'sanitary condition.' It is essentially necessary to insist on 'health condition' as the synonym of 'sanitary condition,' instead of limiting its meaning to such variable portion of health condition for which sanitary authorities choose to recognise their responsibility. Death-rates are, in the main, trustworthy numerical tests of 'health condition,' although they may not be of sanitary condition so limited. The various influences which tend to disturb the value of the death-rate as a test of health condition, and which have been urged as fatal objections to the use of death-rates for such a purpose, are examined and analysed in the paper with the view to determine the extreme limit of their effect. It is shown that the only really important disturbing influence, apart from health condition, is the varying sex and age

proportion of different populations, and for this death-rates may easily be corrected. Without such correction, however, the recorded death-rates of nearly all urban populations are somewhat understated, while those of rural populations are overstated. Thus, the excess of mortality due to the unfavourable health conditions of urban residence is greater than it has hitherto been supposed to be. Death-rates may at all times be compared with the mean death-rate in healthy districts, 17 per 1,000; most of the objections made to the comparison of death-rates in different communities may thus be obviated. As the result of his investigations, Mr. Humphreys considers that death-rates afford a numerical test of health condition sufficiently approximative and trustworthy to be useful in the future, as they have been in the past, as a stimulant of the public interest in health progress. While the death-rate at all ages is held to be sufficiently accurate for the above-mentioned purpose, medical officers of health are urged to give in the statistical portion of their sanitary reports the death-rates of persons living at various groups of ages. Such death-rates at groups of ages have a greater scientific value than the death-rate at all ages, although they are not available as numerical tests of health condition, the public utility of which we cannot afford to ignore.

Dr. Henry Ashby read a paper on the question—

HOW FAR MAY THE AVERAGE DEATH-RATE OF A POPULATION BE CONSIDERED AN EFFICIENT TEST OF ITS SANITARY CONDITION; AND BY WHAT MEANS CAN THE HIGH DEATH-RATE OF CHILDREN BE REDUCED?

of which the following is an abstract.

Statistics show that among the working classes of the large manufacturing towns the number of deaths among infants under one year equal one-third, and under five years equal one-half of the total deaths at all ages. The diseases which are most fatal are bronchitis and pneumonia, diarrhoea, whooping-cough, simple atrophy or malnutrition, and measles. The causes of the high mortality are very complex, and include the influence of the health and life conditions of the parents in producing weakly children, unsanitary conditions of dwellings, insufficient ventilation of rooms, and effects of smoky atmosphere, improper feeding of young infants, employment of mothers in mills, &c., bad effects of burial clubs, poverty, degradation, and drunkenness of parents. The means to be adopted to reduce the high death-rate are: 1. Improvement in the surroundings and homes of the working classes; provision of open spaces; diminution of smoke; improved dwellings; checks on burial clubs and friendly societies. 2. Improvements in the habits and status of the working classes by means of education, and by extension of ladies' sanitary associations for systematic work among the poor.

DISCUSSION.

In the discussion which ensued Mr. B. Latham said that he believed that the death-rate was largely influenced by and corresponded with the prevalence of underground water, which had the effect of reducing it.

Professor Gairdner was of opinion that the proper death-rate for ascertaining the sanitary condition of any place was that of children under one year of age.

Dr. Herbert Page, Redditch, objected to the entrance of children into burial clubs, and thought that the State ought to veto such a procedure, or defer the payment of the sum assured for several years after the child's death.

Mr. Neison, London, denied that the average death-rate was any criterion of the sanitary condition of a place, and suggested that the mean of the rate of mortality in five groups of ages would give a better idea. He maintained that the sickness in a population did bear a proportion to the number of deaths, and said that a national registration of sickness would be most useful.

Dr. Rickards said he had come to the conclusion that a large portion of the deaths of infants in manufacturing towns was due to the fact that they were insufficiently cared for. The State should prevent mothers going to work in factories until their children were of a certain age, and it should also prevent the entrance of children into death clubs.

The Chairman attributed a large portion of the infant deaths to inexperience on the part of the mother, and thought it would be useful for statistical purposes if the number of deaths of firstborn children could be distinguished from the general rate.

Dr. Ashby, in the course of his reply, said that children were no sooner born than some parents or their friends began to think of providing for the burial of the infant, and they were insured in a club or clubs, sometimes for as much as 10s. or 12s.

Mr. Neison said this was against the law, which prohibited the insurance of the life of a child under ten more than 6s.

Dr. Ashby said he believed the law was evaded, and the possibility of evading it and obtaining more money than a funeral would cost, led to neglect of the ailments of infants.

The President (Dr. Chevers) said one remedy might be to prevent any club money coming into the hands of parents for other purposes than those of the funeral and legitimate expenses connected therewith.

Dr. Herbert Page, S.Sc.Camb., of Redditch, read a paper on—

THE SANITARY TEST-VALUE OF THE 'MEAN MORTALITY,' WITH SUGGESTED MEANS FOR REDUCTION OF CHILD MORTALITY,

of which the following is an abstract.

He pointed out that first and most important of those varying conditions which modify the test and impose limitations which must not be overlooked in grasping its true value is the element of time, the relative value of a mean depending on the length of the series of years or groups of events observed, its value increasing as the square of the time. At least, a datum should be taken, especially in small populations, and those where numerous other variants affect the result. In the terse language of Dr. Guy, 'averages are numerical expressions of probabilities; extreme values are expressions of possibilities.' The degree of approximation to the truth should, with regard to the probabilities, be estimated by Poisson's rule, and with respect to the probabilities, by ascertaining the error of mean square, or simpler, by the method of successive means. The effect of the birth-rate, the nature of the sex and age groups of the living, compared with the standard of the 'English Life Tables,' and the local life table, the effect of school lives, of public institutions, emigration, and immigration, and especially the 'expectation of life' of the community, must be regarded. The value of the variants being assessed, the trustworthiness of the mean mortality will be in proportion to the balancing of the extremes, deduced from a sufficient series of observations, and having special regard to the relative sex and age groups of the living to those of the dying; in the same groups, in the same or similar populations. Reverting to the causes and remedies for the high child mortality, the author enumerated the delegation of the care of infants and children to others whilst the mothers were engaged at work, coupled with improper feeding. He suggested that the Infant Life Protection Act should be raised from being a dead letter and enforced by the sanitary authorities; that every person taking charge of an infant or child for pecuniary or other reward or consideration should be required to register her name and address with the local sanitary authority and the registrar, and should be compelled to comply with specific regulations as to character, cubic space (regulating the number of children to be allowed, bed accommodation, washing and laundry appliances, and general sanitary regulations as to light, ventilation, drain-

apply, and systematic inspection; also the establishment at the local expense of a sufficient properly appointed crèches. With reference to the employment of women after childbirth, it should not be allowed within this of childbirth, and that the employers of a wife should be required to deduct a certain amount of their weekly wages to be invested with the wife on her behalf, to be refunded during absence from work; the registration of births, and the delivery by the registrar of a simple instruction in the care and feeding of the more or less continuous presence of zymotic and epidemics being important causes of child life, considering we had advanced, even law, so far as to admit their preventability, it is a failure to civilisation that the provision of infant accommodation was not compulsory, and that the registrar should register the presence of these cases at least as fully as we do those occurring amongst cattle. The effects of the common insanitary defects of dwellings, he was aware of the difficulty of the position of the subject, but thought it must be enacted that no person or community shall be allowed to possess any dwelling contravening the rules of healthiness. Another most important thing, if it does not distinctly bear against—the prevalent custom of insuring the lives of children, by which parents (sometimes others) acquire a pecuniary interest in the death of the child. Even such a possibility is inhuman, and equal. Either no insurance should be permitted under five years of age; or, if permitted, any sum therefrom should not be payable until a year after death, long enough to destroy all interest therein. Again, we urgently require an improved, and simplified method of medical aid into the causes of the deaths of children. First, the agency of medical officers of health be required to secure their official independence and tenure so that they might well be required ex-officio to act as coroners, or assessors to, if not as coroners. An aid should be held in every case where the cause of death is not certified by a registered practitioner, or, failing this, in cases where the cause was ill-observable. He would make, at least, the principal diseases justifiable 'causes' to investigate, authorities should be held pecuniarily responsible in a manner regulated by law for omissions or mistakes connected therewith. Lastly, there was the main cause at the very root of much child mortality which he was afraid we were not yet prepared to seriously consider—viz., some check to prevent the transmission of an enfeebled stock from various causes, alike a misfortune to the offspring, and further endangering succeeding generations, antagonising the highest beneficial and of hygiene, viz., to raise the expectation of the community, thereby securing to it and the greatest good of the greatest number, and growth more perfect, decayless rapid, life more health more remote. Our waste of child life, national and legal-hygienic blot, calls for the consideration of some such measures as here be saving of life which can be undoubtedly and speedily justify the legislative adoption and some such principles.

Henry Urdin read a paper on—

TRACTION FROM PUBLIC USE OF SPACES AND WAYSIDE STRIPS OF

He said that in the last century open spaces were everywhere; and the traveller on horseback not limited to the stony road—he used

the wayside strip of green. The open spaces have now mostly disappeared. Inclosure Acts have converted the larger of them into private property—a process in which (formerly, if not at present) the claims of the poor were little regarded. Many other wayside strips have been inclosed and built on; and in some localities at least the most miserable of the cottages—those destitute of gardens—are found built on these strips. In many other cases the neighbouring owner has quickly enlarged his field by taking in the strip between it and the road. The latter becomes in consequence nothing but a hard and dusty causeway, so many feet in width; and the poor have lost much which might make their lives more tolerable. So far as these spaces are built over the injury is beyond remedy. Where there has been no actual building Parliament might well interfere in two ways—(1) by prohibiting any inclosure of the wayside strips to the extent of 10 feet or 12 feet on either side of the statutory highway; (2) by enabling the local authority to reclaim and recover back from those who have abstracted them from public use the strips fenced in during the last twenty or thirty years. It is not necessary to touch the question of property. Half of the highway now belongs to the adjoining proprietor; but he owns it *sub modo*, and, having once dedicated any way to the public, the latter have the full enjoyment. By an extension of this doctrine of public dedication to open spaces and wayside strips which the public enjoyed thirty years since and have now been deprived of, this growing public mischief may be stopped, and the amenities of life in the rural districts much increased. The 'local authority' must not be the vestry, as over them, either as landlord or as employer, the abstractor of spaces probably has in all places much influence. It should be a more extensive and independent body, such as the Highway or Poor Law Board of the district, until a County Government Bill is passed; and in case of dispute the County Court judge should have full power to adjudicate.

In the Art Section Mr. T. C. Horsfall contributed a voluntary paper on the question—

ARE LOCAL GOVERNING BODIES JUSTIFIED IN EXPENDING LARGE SUMS OF PUBLIC MONEY FOR THE PURPOSE OF BEAUTIFYING TOWNS AND OF PROVIDING PARKS, PLAYGROUNDS, AND OTHER FACILITIES FOR PUBLIC RECREATION, AND, IF SO, WHAT ARE THE LINES ON WHICH THEY CAN MOST ADVANTAGEOUSLY WORK?

The writer took it for granted that everyone believed it to be the duty of the community to provide for each class those things which it could not provide for itself, and could not lack without great injury to the whole community. He held, therefore, that if he showed that through the failure of local authorities to make towns beautiful, and to provide facilities for recreation for the working classes, grave injury had been caused to the whole country, the question he had to discuss must be answered affirmatively. Pointing out that many children in towns did not know how to play, and that a great many ratepayers, having never learnt to care for beauty, either of nature or art, would be opposed to the provision of art galleries, parks, &c., at the cost of the rates, he argued that the help of school managers was needed to teach all townspeople to take wholesome exercise and enjoy beautiful things, and urged that all children should be taught at school how to play games and use gymnastic apparatus. He then recommended that town councils should make existing playgrounds in towns, including those of all schools, out of school hours, of more use by providing them with gymnastic apparatus and well-trained custodians; that covered gymnasia, like one which has been at work successfully in Manchester for the last two years, should be provided for use in dark evenings and wet weather. He said that

town councils ought to provide large towns with an almost complete ring round the towns of open spaces, partly consisting of parks, partly of play-fields; but that there was no chance of work so costly being done, as many ratepayers could hardly afford to pay their present rates, unless the inhabitants of large towns acquired the power of including the suburban districts, the inhabitants of which got most advantage from new parks, within the municipal boundary, without the consent of the inhabitants of the suburbs, and unless the owners of land in towns were made to contribute to the municipal revenues.

THE PRESERVATION OF OPEN SPACES.

Mr. Robert Hunter, M.A., formerly honorary solicitor to the Commons Preservation Society, contributed a suggestion for the better preservation of open spaces. He reviewed the progress of public opinion and of legislation on the subject of open spaces. The principles established—(1) that common land should be preserved in its open condition; and (2) that no opportunity should be lost of providing public gardens in towns. But notwithstanding the strength of public opinion, open spaces were not yet safe, but were liable to be inclosed by the Land Commission, or appropriated for purposes of railways and other industrial undertakings, or inclosed by the lord of the manor. The Commons Preservation Society and other existing agencies were able to cope with the first two of these dangers, but there were no trustworthy means of resisting the third. The remedy which he proposed for these defects in the existing machinery was the formation of a corporate company under the Joint Stock Companies Acts for the purpose of acquiring properties possessing common rights, manors and commons, and town gardens, and of managing all open spaces so acquired in the public interest. In addition to these such an association might ultimately be enabled to arrange without purchase for the temporary use by the public of town gardens, to co-operate with local authorities for the above purposes, to exercise, for the protection of open spaces, rights of common attached to properties purchased, and subject to the foregoing considerations, to manage property for profit. But the central idea was that of a land company which should administer its property with a view to the protection of the public interests in open spaces.

Mr. Vesey Fitzgerald thought it would be very unjust to put a special tax on the owners of property in order to promote the objects advocated in the paper.

Mr. Shaw-Lefevre said that there was no man in the country who knew more about commons than Mr. Hunter. He had been employed in nearly all the great commons cases, and was the solicitor to the Corporation of London in the Epping Forest case, in which between 6,000 and 7,000 acres had been saved for the benefit of the people. Fifteen or sixteen years ago such a task would have been deemed hopeless, but with the assistance of Mr. Fawcett, Sir Charles Dilke, and others, great victories had been won. At all events, we were now safe from legislative interference. By the common law the lord of the manor could not enclose a common except by the consent of each and every commoner. In Epping Forest one lord of the manor had enclosed about 1,200 acres, thinking he had obtained the consent of all his commoners. But the Corporation of London had common rights in respect of a cemetery of about twenty acres, and fought a costly battle for the rights of commoners in which they were victorious. Suits for rights of commons were very costly, and although a few public-spirited individuals had vindicated the rights of the people, the work of commons preservation could only be carried on by associated effort. He was disposed, therefore, to welcome the suggestion of Mr. Hunter. He should be disposed to go so far as to require the sanction of Parliament to every scheme of inclosure on the part of a lord of the manor, though he was afraid that however willing the House of Commons would be to agree to such a proposal, it might not be so acceptable in another place. But what was now wanted was not so much large spaces

as a number of small ones for play and recreation grounds. Twenty or thirty commons averaging 160 acres each had been rescued about London. He would also suggest that corporations ought to have the power, which the Corporation of London had recently exercised, of acquiring more land than was needed for the purpose of a park or recreation ground, in order to dispose of the superfluous land at its improved value. By a recent Act of Parliament (see SANITARY RECORD for September 15, p. 86), disused burial grounds could no longer be built over, which was a great boon to the crowded parts of towns.

Mr. Sturge advocated the repeal of the Mortmain Acts for the purposes referred to in Mr. Hunter's paper.

Mr. F. Safford urged the Commons Preservation Society to take up the question of footpaths.

THE OUTBREAK OF TYPHOID FEVER AT KIDDERMINSTER.

THE town of Kidderminster, a parliamentary and municipal borough, with a population of some 28,000, situate on the banks of the River Stour, and known throughout the civilised world for its carpet manufactures and other similar industries, has, during the last six weeks, been the scene of one of the most serious and extensive epidemics of typhoid, or enteric fever, ever known in the Midlands. As in most cases of the kind, when once the gravity of the attack became known, a tendency was at once manifested to exaggerate the evil, and to let dismay and terror run riot with reason and common sense. The wildest rumours got afloat both as to the causes and the extent of the outbreak, and remedies were proposed during the earlier period of alarm which were not of the most practicable nature, would have involved the town in ruinous expenditure, and probably have effected no good. Typhoid, enteric, or pythogenic fever, as this particular form of disease is variously named is one of the preventable class of diseases, and generally arises from the inhalation of foul air or sewer-gas, the drinking of impure water or contaminated milk, and is essentially a consequence of sanitary neglect. Anything approaching an epidemic of this particular disorder cannot consequently occur without throwing grave responsibility upon the local authorities, and pointing to some great sanitary defect or neglect. Now that the excitement and apprehension which followed upon the public knowledge of the magnitude of an evil, the source of which could not be satisfactorily ascertained, has calmed down, and people have the opportunity of forming conclusions based upon the investigations of competent and scientific authorities, the causes of the epidemic and the remedies most likely to be efficacious are more clearly discernible. It was at the monthly meeting of the Town Council, held on Sept. 3, that Mr. D. Corbet, the Medical Officer of Health, in a supplementary report, stated that since his monthly report had been made up, a sudden outbreak of typhoid fever had appeared in the town, not confined to one district, but prevailing generally. From 80 to 100 cases had broken out, fresh cases were occurring every day, and there had already been seven or eight deaths. He was not prepared then to state the origin of the outbreak, but was inclined to put it down to sewer-gas, and he recommended that the sewers be constantly and freely flushed, that disinfectants should be used both about the sewers and in the watercarts, that the sanitary inspector visit every case of typhoid to see the conditions under which it occurred and that the proper sanitary measures were used, that the water-supply be tested by analysis, and that the infectious diseases hospital be opened free to all but pauper cases. On the 11th he reported that fresh cases continued to arise, that the conditions of the outbreak were such as to place its source outside milk contamination, that the water had been analysed with a satisfactory result, and that he was of opinion the cause arose from want of sufficient ventilation for the sewers, forcing gas into the houses and

adjoining premises when the sewers were flushed, owing to the immense quantity of water discharged into them, and the defective manner in which many of the drains were trapped. Up to that date there had been 200 cases reported and 14 deaths registered. On September 22 he reported a death-rate for the month of 40·784 per 1,000, as compared with 29·058 for the previous month, and 13·765 for the corresponding month last year. Of the total deaths there had been 18 from diarrhoea, as compared with 19 the previous month, and 27 from typhoid. At the monthly meeting of the Council, held on October 1, he reported that the total number of cases reported up to that time was considerably above 600, and that the total number of deaths was 44. Since then the deaths have increased to nearly sixty. Such a condition of things in a town like Kidderminster, occupying a low-lying position and covering a comparatively small area, was naturally calculated to create alarm. This feeling, however, was much intensified by special articles which appeared in the *Birmingham Daily Post*, in which an attempt was made to trace the source of the outbreak to a contaminated water-supply, the onus of such contamination being laid upon the sanitary authorities themselves. One of these articles was accompanied by a diagram showing how the water-supply, according to the theory set up, was polluted. Kidderminster, like too many other towns in this part of the country, is largely dependent upon the filthy midden system, and a large number of these are uncovered, and are admittedly in a very insanitary condition. But a number of the better class houses are provided with water-closets, which, it has transpired, are directly connected with the town sewers. For the treatment of the sewage that passes through the sewers, a sewage farm has been put into operation. This is situate on the Stourport Road, and the sewage is pumped to the requisite level from works situate within seventy feet of the well from which the town is mainly supplied with water. The pipe conveying the sewage from the pumping-house to the sewage farm passes close alongside this well, and at a joint in this pipe, fifteen feet distant from the well, a slight leakage or 'sweating' was alleged to be going on, sufficient to cause a dampness of the surrounding soil. The inference drawn was, naturally enough, that the leakings from this faulty joint in the sewage conduit percolated into the well from which the water supply of the town was principally obtained. Such a suggestion of course produced considerable uneasiness in the minds of the townsfolk, inasmuch that if this was really the cause of the outbreak of fever, there was no knowing to what extent the seeds of the disorder had been sown. Nor was this all. At a distance of about ten feet from the well was a disused collecting tank for sewage, in which there was stated to be between three and four feet depth of foul stagnant water, of a dull greenish tint, the soakage of the adjacent soil, showing the pervious nature of the ground, and the ease with which percolation from the leaky joint to the well might take place. It has also been stated that the site where the sewage works now are was formerly a brick-yard, and that the pits which had been dug for clay were afterwards used as 'tips' for night soil and rubbish. Obviously the first duty imposed upon the authorities under these circumstances was at once to ascertain whether such percolation really did take place, and, if so, to what extent; also to thoroughly test the quality of the water by analysis. This they lost no time in doing, and an analysis of the water was made by Mr. Jones, the borough analyst for Wolverhampton, as follows: 'Grains per imperial gallon, or parts per 70,000. Total solid matter, dried at 212° F., 14·080; free or saline ammonia, 0·000; organic ammonia, 0·0010; nitrogen as nitrates and nitrites, 0·1485; chlorine, 1·470; oxygen, absorbed in four hours at 80° F., 0·0010; colour through two feet a very pale greenish tinge; total hardness, 11°·16. The analysis shows your water to be in a perfectly satisfactory condition.' Mr. Comber, C.E., the

borough surveyor, in a report dated Sept. 9, demurred to the statements that the outbreak was caused either by sewer gas or pollution of the water supply; but made a sweeping indictment against the middens. 'There is no doubt,' he stated, 'that the present partial system of middens is a fruitful source of disease. The excreta from fever patients is in many cases thrown into them without any previous disinfection, and perhaps a whole row of houses are common to one midden. When emptied, the liquid contents saturate the yard where thrown out. The street and channels, and frequently the gully grates, receive some of it. It is then carted through the town, with the risk of some of it being spilled and sowing infection broadcast. I consider the whole of these disgusting places should be swept away, and proper water-closets and dry ashpits substituted. Until this is done the health of the town will not be satisfactory.' However much we may be disposed to agree with these remarks, which recommend themselves, the report left the cause of the outbreak an open question, for the midden system could scarcely be held responsible for the almost simultaneous appearance of the disease in all parts of the town, and the rapidity with which it spread. The Mayor (Mr. D. W. Goodwin) then telegraphed to the Local Government Board to send down an inspector to investigate the matter, and on September 22 Dr. Parsons visited the town, and, in company with the Mayor, the surveyor, and other officials, inspected the well, the sewage pumping works, and the section of the pipe containing the joint from which the 'sweating' was alleged to proceed. He also examined the apparatus used for flushing the sewers, and held a conference with the medical men of the town. As the result of this visit the Town Council received a letter from the Local Government Board on the 26th ult., which stated that Dr. Parsons had reported to them the result of his visit to the town, that they learnt that the situation of the well at the sewage works rendered it liable to the risk of very serious pollution, and noted with satisfaction that the Council proposed to sink a second bore, in addition to prolonging the suction-pipe 50 feet, and to fill in the space between the pipe and the side of the bore-hole with concrete. They could, however, only regard that as a temporary measure, and were of opinion that the source of supply should be discontinued as soon as practicable. They also hoped the sanitary authority would take active measures for efficiently dealing with all sanitary defects which might be discovered during the inquiries it was proposed to make as to the sanitary surroundings of each house in which a case of enteric fever has occurred or may occur. So far as this communication goes, indefinite though it is, the only department upon which suspicion is thrown, by inference, is the water-supply from the well near the sewage pumping works. Formerly the water-supply of the town was pumped from a well sunk into the new red sandstone, about a mile and a quarter out of Kidderminster, on the Stourport Road, the works there being opened in 1872. But the supply proved inadequate, and the surveyor was instructed to prepare an estimate and scheme for a new bore-hole at the sewage works, as an auxiliary supply. This was done; and tenders for carrying out the work were ordered to be obtained at a meeting of the council at which twenty out of the twenty-four members were present. The water obtained from this well was analysed from time to time, and reported to be equal to that which had been obtained from the artesian well at the water-works, the analysis in September 1880 being that it was 'an exceedingly good water, well suited for drinking and general domestic purposes.' This source would seem to have gradually come to be that from which the town is principally supplied, the well being pumped night and day, while the old well is only pumped eleven hours out of the twenty-four. With regard to their sewerage arrangements the authorities cannot be charged with idleness. In ten or twelve years they have expended 120,000*l.* in their endeavours to secure an efficient water-supply and drainage

system, and they certainly seem in this instance, as soon as they recognised the gravity of the position, to have taken such steps as would enable them to grapple with the difficult and onerous task so suddenly thrust upon them. At the meeting of the council held on the 1st inst., while deprecating the sensational reports and statements which had been made, and which, while doing no good, caused unnecessary and dangerous alarm, the serious nature of the case was fully admitted, as well as the necessity for such prompt and effectual measures as would stamp out the present attack and prevent a recurrence of it. The Mayor does not seem to have known previously of the situation and surroundings of the well at the sewage works; but as soon as the possibility of sewage getting into the well was mooted, the pumping was stopped and recourse was had to other sources for the water-supply. At this meeting a lengthy report was submitted by Mr. E. Pritchard, M.I.C.E., F.G.S., the well-known authority on sewage matters, in conjunction with the borough surveyor, upon the general sanitary arrangements and water-supply of the town. The report attributes the cause of the outbreak to sewer-gas or polluted water, or both, condemns the middens and slaughter-houses, some of the latter of which drained directly into the sewer, and states:—

‘Our inspection of the sewerage arrangements, both as regards the construction of sewers and house-drains, prove them to be most defective, and in their present condition positively dangerous to the health of the public, some of the sewers being laid with a reverse fall, allowing the organic matters therein contained to decompose and evolve deleterious gases, when frequently the only method of escape for such gases would appear to be directly into the dwellings, there being no ventilation of either sewers or house-drains; at least, more correctly speaking, ventilation is the exception and not the rule, although water-closets have been generally adopted in the higher parts.

‘Our inspection of the slaughter-houses and back-yards shows the existence of a most offensive and disgusting state of things, the condition of many of these places being sufficient in themselves to create sickness.

‘Before offering our conclusions and recommendations as to what is absolutely necessary to be done, it is desirable that due consideration be given to the nature of the sewage discharged from the various manufactories and other places into the sewers. The sewage in itself is of a very offensive description, but is greatly intensified by the discharge of nearly all the liquid refuse at a high temperature from the mills constantly during the day. This has the effect of rarefying the gas given off by the sewage, and renders absolutely necessary a more comprehensive system of sewer ventilation than what is required in other towns not similarly conditioned, whilst many manholes to the sewers are provided with a catchpit, or sump, thus allowing solid matter to be arrested and deposited, which, if not constantly removed by mechanical means, adds to the nuisance.

‘Under these circumstances we would therefore recommend that immediate attention be given to the following suggestions, which, in our opinion, when considering the health of the public, are absolutely essential to be at once carried out.

‘1. That no further supply of water to the town be taken from the supplemental well in New Road, at the Caldwell pumping-station, until structural alterations have been effected, and that by means of iron pipes carefully inserted into the bore-holes, with proper connections direct from the suction-pipes of the pumps, and the whole of the well surrounding such bore-hole carefully filled with cement concrete, and then pumping only, as a temporary measure, direct from the bore-hole, instead of, as formerly, from the well, at the same time frequently determining by analyses the purity of the water so taken.

‘2. In consequence of the water-supply to Kidderminster being at certain times insufficient, that another well and bore be constructed, together with the necessary pumping power, at a point to be hereafter determined.

‘3. That the high level reservoir be cleansed and covered with masonry or concrete, as in its present condition it is unsuited for storing water pumped from the deep sandstone formation; also that a high level service reservoir be constructed.

‘4. That the supply of water be constant, and that no direct connections between the distributing pipes and water-closets be permitted; also that arrangements be so made, with existing flushing cisterns, so as to effectually preclude the possibility of access of sewer-gas to the water pipes.

‘5. That immediate ventilation be given to the sewers by means of open gratings at the surfaces of the streets, or roadways, one hundred yards apart, such gratings to be constructed to prevent the admission of detritus to the sewer. By the construction of these ventilators air will be admitted to the sewers, which is as great a necessity in underground ventilation as the openings are for the exit of air, thus forming a series of upcast and downcast shafts, and where the sewers are properly constructed, and regularly flushed, the diluted sewer air, discharged at the ground, will be rapidly diffused and deodorised by the atmosphere.

‘6. That the sewer in Park Lane, having at the present time a reverse fall, be relaid in a proper manner, as well as such other sewers in the town as may be found to have an insufficient inclination.

‘7. That the catchpits or sumps at the bottom of man-holes be filled in the semicircular earthenware, or brick inverts, level with the outgoing sewer, be constructed.

‘8. The disconnection of house-drains with sewers where practicable, and the ventilation of all soil pipes and traps of water-closets. Such house-drains to have between the house and the sewer, a trap and downcast shaft combined, as also a gully trap and grating, and so arranged that there shall be no connection between the ordinary slop-stone and the house-drain.

‘9. In consequence of the natural tendency of sewer-gas to rise to the higher points of the town, the sewer system to be ventilated in sections, by the construction of flaps upon sewer outlets in manholes, so that no one particular district shall ventilate the sewers of another district.

‘10. That surface-water, where practicable, be diverted by the existing gullies and surface-drains to the river, and so reduce the difficulty of dealing with the sewage and lessen the annual cost at the outfall; also that manufacturing refuse, so far as possible, be prevented from entering into the sewers.

‘11. The construction of additional self-acting flushing chambers, where the flow of sewage is sluggish, consequent upon the flat gradient of sewers.

‘12. That the present system of middens, which is both insanitary and dangerous to health, be at once substituted by proper self-acting trough-closets, and that all receptacles for ashes and other refuse be constructed above the ground level and covered.

‘13. That the keeping of pigs in the thickly populated portions of the borough be prohibited.

‘14. That a public abattoir be constructed, and all private slaughtering of cattle and pigs be prohibited; also that immediate closing of some of the more objectionable ones take place.

‘15. A great number of small houses, from their want of drainage, bad state of repair, and other unsanitary conditions, are little less than hotbeds of disease, and should be immediately declared totally unfit for human habitation, and closed accordingly. No doubt such suggestion, if acted upon, would inflict a serious hardship upon the owners, and is such an exceptional case as may be fairly considered by the Town Council.’

The report was adopted, and measures are to be taken to put the recommendations in force at a probable expense of more than 10,000*l*. It is satisfactory to know that the epidemic is on the decline.

The views the medical men of the town take of the

subject will be gathered from the following resolutions, passed at a meeting at which there were present Dr. Roden (in the chair), Mr. S. Stretton, Dr. Langford, Messrs. David Corbet, J. W. Colbourn, J. Lionel Stretton, and Dr. Measures. A prolonged discussion took place, and there was a minute investigation of all circumstances bearing upon the causes of the epidemic. The following resolutions were unanimously agreed to:— (1) 'That, while we are unable to state positively the cause of the epidemic, we are of opinion that it was primarily caused by the water-supply, and that it has been aggravated by the imperfect drainage system and other insanitary conditions, and that there is no evidence against the supply of milk.' (2) 'That from the evidence produced we are of opinion that the well at the sewage station should be immediately closed, and not used again under any circumstances whatever.' (3) 'That proper provision should be made for the certainty of pure water in the reservoir, including the raising of the surrounding wall and the adoption of a proper covering.' (4) 'That immediate steps be taken to provide an additional supply of pure water at a distance from the town.' (5) 'That the drainage system be fully investigated by an eminent sanitary expert, all levels, catchpits, and ventilation to receive his especial attention.' (6) 'That all junctions with the main sewers be examined and certified as being in rigid order, by the Corporation officials.' (7) 'That a public abattoir be constructed without delay, and that all intramural slaughter-houses be abolished.' (8) 'That all middens and privies be abolished, and that no pigsties be allowed in the close confines of the borough, and that some measures be taken to mitigate the emanations from obnoxious trades.' (9) 'That, in the meantime, the free use of disinfectants should be proceeded with, including the flushing of all drains and watering of streets with the same.' (10) 'That the Infectious Hospital be placed at the disposal of the medical profession for the admission of all such cases as they consider desirable, and that such admissions be obtainable with the greatest possible ease.' (11) 'That a thousand handbills be printed for distribution amongst the fever cases, with suggestions for the care of the patients' nursing, disinfection of secretions and linen, proper feeding, and dealing with milk and the water.' (12) 'That a fund should be started for the provision of nurses, to devote their time to visiting the sick poor under the guidance of the medical profession.'

Since the above was written a requisition has been presented to the Mayor asking him to call a town's meeting at an early date to consider the present serious state of the drainage and water-supply of the town. Considerable inconvenience has been experienced by reason of the stoppage of the water-supply from the well at the sewage works, the supply from other sources having run short on several occasions. Though fresh cases still occur, they are of a mild nature.

THE MEDICAL AND PHARMACEUTICAL EXHIBITION AT HUMPHREYS' HALL, KNIGHTSBRIDGE.

THIS Exhibition was opened on Monday, and will remain open until Nov. 12. It is under the patronage of the authorities of University College Hospital, to whom the surplus will be given after the expenses are paid. Writing at the moment of going to press, the reporter can give only a mere outline of the exhibits. Many of the leading manufacturing chemists and surgical instrument-makers are present, as well as makers of apparatus for inhaling nitrous and oxygen gases. Good preparations are also fairly represented. Medical glass and aerated water-bottles, mineral waters, lime juice, &c., find allocation, and many articles of domestic use bearing upon health are amongst the exhibits. But the principal feature, and one to which the attention of the medical profession will be drawn is a Portable Iron Hospital, erected by Mr. Hum-

phreys under the supervision of the authorities of University Hospital and furnished by them, nurses being in daily attendance to explain the various appliances, &c. As this hospital will be described in detail in our next issue, with illustrations, it is only needful now to note that it is a most complete building, and shows how corrugated iron can be made to do duty for hospital purposes, either for temporary or permanent uses. There are two wards, each large enough for six beds, with kitchen, scullery, bath rooms, and w.c.'s, matron's room and sleeping room, and everything is built up in the most substantial manner, though easily taken to pieces for re-erection. Since the National Health Society held their exhibition at Humphreys' Hall in June 1883, the fine pile of buildings then in course of erection by Mr. Humphreys is nearly completed, and the principal hall is enlarged. The public are admitted free of charge to this exhibition from 10 A.M. until 1 P.M., after which, until 8 P.M., the charge for admission will be one shilling.

NEW INVENTIONS.

ARTIFICIAL GRANITE PAVING.

WITH the different kinds of artificial stone coming more or less into use for paving, it appears somewhat singular that a system of laying more after the style of the ordinary 'flags' has not been generally carried out. With one or two exceptions all that have come under the notice of the writer have been set in one continuous length as asphalt, or in blocks of such size that they could not be taken up without breaking. This adds to the expense very much, besides keeping the work of relaying about longer than necessary to the great detriment of street traffic and shopkeepers. In the case of asphalt this has become a great nuisance, as it must be remembered that there are gas-pipes, and in many instances water-pipes leading to every house, these being bedded in and not to be got out except by breaking up the pathway again. This difficulty belongs to any artificial substance laid in the manner mentioned. The writer recently paid a visit to Ealing to inspect some artificial granite paving that has been laid for five years, and the principle adopted appeared to him to be an admirable one, while the cost of the pavement is less than asphalt, or any artificial substance save tar-paving, which is not likely to be used except for suburban traffic. It is much less than that of York flags, to which it bears a close resemblance. This paving, which is laid by Mr. Taylor, of Church Street, Chelsea, is chiefly composed of the small chippings of granite received direct from the quarries. It is laid on the spot in blocks about two inches thick and about the size of ordinary flag-stones. Wherever a pipe occurs that may necessitate the paving to be removed at times, provision is made for this at each side of the block, so that when one is raised the others can be removed with ease; for it is one of the advantages of Mr. Taylor's arrangement that each of these blocks can be taken up without breakage, as a solid flag-stone. It is unnecessary to dilate upon the merits of such an arrangement, as its economy and simplicity must be apparent. Looking to the wearing qualities of granitic pavement there is none other save asphalt that is so enduring, and the feeling of safety to the pedestrian, offered by the artificial granite, is superior to all others. It is, the writer is informed, some eighteen years since Mr. Taylor introduced this substance, which he has laid extensively in the brick form as a flooring for stables, &c., with great success. It is therefore difficult to understand the indifference shown in reference to Mr. Taylor's invention by vestries and similar authorities, since it is calculated to provide a better and more economical pavement than can be obtained in a large majority of our towns.

VENTILATION BY SYPHONIC ACTION.

MR. C. MAITLAND TATE, a civil engineer of much experience, has invented a new form of ventilation, which consists of a syphon ventilator that may be portable or form a part of a complete system of ventilation for the whole of a house as an extractor, and an air filter also on syphonic principles, as an inlet for fresh air. This system Mr. Tate has aptly named 'Aids to health and comfort.' Taking the air inlet for description first, there is a deodoriser, and an air purifier contained in a small box, of which an illustration is appended, and through which all air entering the apartment through its agency must pass. This box, it will be seen, consists of two compartments, A and B, and

a passage underneath. To whatever this box is attached, compartment A is outside and B inside. A is filled with small lumps of charcoal, and B with layers of cotton wool placed loosely in it. Although not a syphon as we generally understand—viz., a bent tube—the action is undoubtedly syphonic, as the air entering at A has to pass down through the charcoal, where it is deodorised, through a perforated bottom into the passage, whence it rises upwards and is filtered through the agency of the cotton wool in B, entering the apartment perfectly clean and pure. If any doubt should exist as to the truth of this, the sceptic has only to examine samples of cotton wool that have been in use a week or two, when his misgivings will be quickly set at rest. The top of the compartment B is also covered with a perforated lid. The utility of this process will be acknowledged by persons looking at our next illustration, which shows a fireplace with a board fitted to it, to which is attached the purifying box or

filter at the bottom. The advantages of fresh pure air in a bedroom cannot be over-estimated, and in the case of invalids it is still more valuable. The cost of this portion of the invention is comparatively insignificant. The effect of this apparatus is to purify the air that enters the room, so that however impure the air may be in any locality, persons using this invention are sure to be supplied with wholesome air to breathe at all times, and owing to the minute subdivision of the air, by means of the perforated lid of the filter, without any perceptible draught.

As in an ordinary syphon, when the long or delivery leg is lengthened, the flow increases in velocity; so in the air filter, the more air that is consumed in a room the greater does the supply become, hence the supply always equals the demand. The same mode may be carried out by means of the door of a room, by filtering

the air coming in from the hall or landing, or fixing a tube just under the window, as shown in accompanying illustrations. Another mode by which

invention can be utilised is by means of a pedicel shown in the next illustration, where the air is brought from the outer atmosphere to the bottom of the pedicel passed through the same purifying medium, and is ad-

to the room through perforations in the four upper panels, the top being left free for a vase of flowers or other ornament. The extractor for the foul air is at about 6 feet from the floor, and can be made of any variety of ornamental designs. From the opening is carried down a certain distance, finishing in an upward bend or syphon, which may be carried to the chimney in any suitable mode of exit. There are two ways of effecting this. To use technical terms, either a long leg, or a short leg is required; that is to say, if the tube can be of sufficient length, the natural action is alone sufficient for the purpose; but, if this cannot be obtained, a slight current of heat, even a candle or small lamp, to produce an upward current is necessary, and without going into detail can be arranged in a variety of simple ways. Mr. Tate also provides an entire portable apparatus, that can be easily carried by any person and removed from the room for the purpose of ventilating it and purifying it in connection with the fireplace, which must prove of great value, particularly in the case of sudden illness, or when a room has not been used for some time. In addition to the unerring action of the syphon, there are palpable advantages in the sectional application of Mr. Tate's invention. This system has been successfully applied to the ventilation of broughams and other close carriages, and is equally applicable to large passenger vessels, either steam or sailing, and to yachts or other pleasure boats. The different applications of the system can be seen at No. 10, Ke-

Town Road. Both the ventilator and filter can be made of any suitable material and rendered ornamental as pieces of furniture.

NAIL-LESS WOOD FLOORING.

AMONGST the changes partaking of a sanitary character that are gradually finding their way into our homes, the supplanting of the time-honoured 'Brussels' or 'velvet-pile' carpets, covering the entire floor, by square Turkish or Indian carpets and rugs partially covering the floor is not the least notable. But this change is not pleasing to the eye where the old flooring boards, even when stained to imitate oak or other woods, are left down with their gaping interstices. To obviate this objection, Mr. Samuel Putney, of the Baltic Wharf, Harrow Road, has introduced an excellent flooring, which, when laid down, presents a perfectly smooth and close surface, as even and close as a parquet floor, and at a moderate cost in excess of deal flooring. Though called a nail-less floor, it is not so in the strict sense of the term, as the illustration shows, but the advantage is that what few nails may be necessary (and they are very few) are out of sight, and it will be seen by the engraving, which is a sectional one, how the one board

recommendation. As an inexpensive and durable fancy flooring Mr. Putney's invention deserves public patronage. It has been laid down in the new building of Madame Tussaud & Sons in the Marylebone Road, which will prove a good test as to the points of advantage commented on.

THE CRAPE OF HEALTH UNDER-CLOTHING.

FOR some few years past under-clothing bearing the above title has been manufactured by Herren Straehl & Co., of Zofingen, Switzerland, which possesses commendable features, and is now being introduced into the United Kingdom. The garments, which consist of the usual kinds for men, women, and children, are made of pure silk, silk and wool, and all wool, in different strengths for various climates and seasons. The peculiarity of the clothing is in the modes adopted in the weaving, which, as its name suggests, partakes of a crape-like character, and is composed of a series of slightly raised ribs, presenting a more extensive space for evaporation, owing to the porosity of the web, than is offered by the ordinary mode of weaving. It is therefore calculated to absorb the perspiration more quickly, and its curly texture, though not in the slightest degree irritating to the most sen-

covers the other, hides the nails, and presents a perfectly close surface. In addition to the flooring, another section is prepared by Mr. Putney for wainscoting or dados, of which is also presented an illustration. So far as the flooring

sitive skin, tends to keep up a gentle friction, calculated to promote its healthy action. This clothing possesses a peculiar elasticity, which, while causing it to adhere to the body, is of so mild a character as scarcely to be per-

is concerned, besides the advantages already recapitulated, there are others not less considerable. It must be palpable that accumulations cannot form, and from the solidity (thicker boards being required) exhalations from lower floors are kept back. The designs of the nail-less flooring are necessarily limited, and unless 'broken up' in certain parts are confined to what may be termed 'ribbon' patterns, or longitudinal strips of different coloured boards. Apart from its ordinary uses, it offers advantages as a flooring for temporary hall or other rooms; the ease with which the boards are laid down and taken up, coupled with their effective appearance, being a strong

ceptible in wear. The garments are supplied of the natural colour; consequently danger from poisonous dyes is avoided. Although, as a rule, all-wool garments are to be recommended, there is no objection to the silk and wool; and in summer many persons would prefer the all-silk garments. There is much to be said in favour of each, and all may be recommended as healthful wear. A notable feature of the Crape of Health is that it does not shrink in washing, although the mode of cleansing is partly by boiling. These undergarments may be ordered through any draper or hosier; the wholesale agents are Messrs. Howell & Co., 60 Watling Street, E.C.

NEW DUSTBIN AND CINDER-SIFTER.

SOME little time since attention was drawn in the SANITARY RECORD to a new Dustbin and Cinder-Sifter introduced by Mr. J. P. Cook, 34 Snow Hill, E.C. As the method of removal of dust from our large and populous centres is still a very vexed question, and has, in connection with the Health Exhibition, been recently made a prominent topic, a recapitulation of the merits of the useful and efficient apparatus illustrated below will not be out of

place. Its salient features are, first, that it combines a cinder-sifter and dustbin in one conveniently-sized apparatus, it being so arranged that the contents thrown into it must pass through the sieve, with the result that the cinders are arrested and may be easily removed for further use, while the dust and refuse fall below; secondly, it is large enough for a few days' collection, but, running on wheels, it may stand in any out-of-the-way place, and when full be taken straight to the dust-cart and emptied without the least nuisance; a matter of no little importance considering the mess and litter usually made by dustmen. It is eminently adapted for workhouses, or, in fact, for any public institution, while 'materfamilias' cannot but pronounce it to be an useful invention. Three or four of these cinder-sifters have lately been supplied to Her Majesty's prisons at Perth and Edinburgh.

PEARSON'S PATENT 'WATER ECONOMISING' CLOSET.

MESSRS. CAPPER, SON, & CO., of Ingram Court, Fenchurch Street, the proprietors of Pearson's 'Twin Basin' closet, which has had such exceptional success, have recently introduced a new closet (illustrated below), named as at head of this notice. It is designed to meet the

requirements of the water companies for a simple and effective valve-closet. A special feature in the invention is that the valve-box is made in one piece of glazed earthenware with the basin, which prevents corrosion, as in the case of the usual metal ones, and the seating of the valve

which retains the water in the basin is also of earl. The other commendable feature is the absence of water-waste-preventing cistern, the arrangement of the flush being performed by a new patent double valve, noiseless in action, and fitted under the seat appears to be unerring in action, and, it is said, 'equally well under high or low pressure, insuring after-flush. The idea of making all the parts of ware is new in valve-closets, and cannot fail to be appreciated.

SAWYER'S PATENT INTERNATIONAL FILTERS.

A CHALLENGE of a very bold character will be the advertising columns of the SANITARY RECORD. Sawyer's Patent International Water Filter (Adelaide Street, London Bridge. Exception may be made by some makers to a competitor taking such a view they may consider that as their filters are supported under test by the jurors at the Health Exhibition should be sufficient; but challenges by private by no means rare. Our columns will be open suggestions filter manufacturers may think proper on the subject, and a copy of this issue of the RECORD will be posted to every known filter in this view.

A sectional illustration of the Sawyer filter is by which it will be seen that it is of very simple construction. The unfiltered water is placed in the top

from whence it flows down a central pipe interior of a hollow cone-shaped block of material, the weight of water above forcing it through the walls of the filtering body and the loose to the centre compartment, a perforated plate into from whence it is drawn off for use. The bottom of the chamber in which the filtering medium is placed, is sunk or dished, which collects matters held in suspension by the water, and their coming in contact with the filtering block, placed underneath or brought to the front, as illustrated, enables it to be drawn off daily. strictly carried out, a cleansing of the filter may be to take place every twenty-four hours, a desideratum devoutly to be wished. The filtering medium, for the hollow cone-shaped body, is either of fine charcoal, or a patented material, composed of ingredients, of which the company are patentees loose material around is granular charcoal. An important point in this filter is that the whole--including chambers for filtered and unfiltered water--is in one piece of earthenware, so that leakages between cannot occur, and no artificial joints or connections to be made. To put in the filtering medium the filter is turned upside down, and, when filled, an earthenware is fixed over it and secured by cement. The much stress upon the easy mode of cleansing and maintains that if this is attended to, the filter will pass pure water, no matter what the source from which the unfiltered supply is obtained, for five years,

ply of material will be required. This assertion cannot be tested; but there are commendable in the construction of the Sawyer filter that are of consideration.

CORRESPONDENCE.

VENTILATION AND VENTILATORS.

subject leads to more controversy than any other with building for the reason, we suppose, that, but not seen, and few professional men take the trouble to learn the laws which govern the direction of winds. We are indebted to Mr. Sampson Low, Esq., for the following remarks on the subject, which commend themselves to us on account of their fairness. The desire evinced to discuss the subject and to much of the misapprehension which, partly from ignorance, and partly through the wilful misstatement of interested persons, exists in the minds of the public. The great agents upon which we depend for natural ventilation are three in number. First, the diffusion of gases. Secondly, the power of the wind which occasionally has to be 'manipulated,' and which is the advantage of using automatic ventilators, and, thirdly, the movements produced by the difference in the columns of air at different temperatures.

It is a well-known fact, of course, that every gas 'diffuses' inversely as the square root of its weight; but perhaps the general public are not so well acquainted with the following fact, that this tendency to diffuse is so great as to take place even through brick walls—of course the amount of 'ventilation' which is effected in this way is practically nil, but 'diffusion' comes a very important factor in ventilation, as we come to deal with 'inlet' and 'outlet' shafts. The wind may be utilised directly as a ventilating agent by 'perflation,' but it is not in that way that it affects our present subject. When a body of air is in motion (or in other words when the wind is blowing) it sets in motion all the air in its immediate neighbourhood. Air is propelled before it, and it causes a partial vacuum on either side of its path, towards which vacuum the air of the vicinity flows at (or nearly at) right angles. As a result, the upward current in chimneys and ventilators is obtained.

The wind may, however, by the pressure which it exerts, mounting often to 8 ounces to the square foot, or pressing down the orifice of an open shaft, impede the wind, and in such cases the utility of properly-constructed ventilators is manifest.

The air in any compartment may be heated by a fire or by a lamp, or, if it be impregnated with vapour, it will rise, and if there be any outlet, part of it will escape, and the air which remains will be lighter than an equal volume of the air external to the compartment: the external air will then rush in through every chink and crevice, and equilibrium is established.

Again, it is a very important factor, which, if we allow it so to do, will assist us much in providing a perfect system of ventilation.

If we briefly considered the natural forces which assist us in ventilation, let us now inquire into the real use of ventilators. All that should be expected of these instruments is that they should materially assist the natural up-current, and prevent the wind from blowing down a pipe (i.e. prevent the wind from temporarily stopping the natural air current) by deflecting it and making it pass over the orifice of the ventilator, thus securing the good effects of the wind and guarding against

its downward pressure. They seek to assist the exhaust current, we take it, by offering to the wind a larger orifice to extract from than would be afforded if the shaft terminated in a plain open end. They seek to guard against the ill effects of the wind by deflecting it (by means of 'Louvers,' 'domes,' 'cones,' and other contrivances too numerous to mention) and causing it to pass straight over such extracting orifices (or orifice) as may exist in the ventilator.

Automatic ventilators may, we think, be conveniently divided into two main groups—

A. Fixed-headed ventilators.

B. Revolving or rotating ventilators.

And we may again subdivide A into—

A.—1. Ventilators using the extracting power of the wind horizontally.

A.—2.—Ventilators using the extracting power of the wind vertically.

Whilst group B may be classed—

B.—1. Cows revolving on the Archimedean screw principle.

B.—2. Cows rotating on fixed bearing-points.

With regard to unfortunate 'Group B,' in general, the following are very great disadvantages:—The friction caused by the constant rotation. The constant wearing away of 'bearing-points,' &c., and liability to get out of order by 'canting' to one side, &c. Requiring attention in the shape of oiling and so forth.

When we come to consider the efficiency, or the reverse, of the 'Archimedean screw pattern' of ventilators, we are led to propound to ourselves the following problem:—Under favourable conditions the up-current in a plain upcast shaft (of say 9-inch diameter) is 500 feet per minute; to obtain this speed (or, in other words, to allow this amount of air to pass), at what rate would a 'screw' of this pattern have to revolve? Shall we say thirteen times per second?

With regard to arriving at the relative merits of the many 'fixed headed' ventilators which are now offered to the public, we are met at the outset of our inquiry by the great difficulty of the various sizes of 'heads' which we see attached to—say a 9-in. diameter pipe—and to attempt to arrive at any accurate relative results from the discrepancies arising from this source is like comparing the results obtained from one engine whose driving wheel is 8-feet diameter with the results obtained from another having a driving wheel of 4-feet diameter.

Mr. Low has long been endeavouring to promote a scheme for testing the relative merits for all fixed head ventilators, on some basis of equality, the outlines for which we append,

1. That the ventilators should be tested on the U tube system.

2. That the same anemometer be used throughout the testing.

3. That the term 'Ventilator' be understood to mean 'the apparatus from the point where the plain shaft ends, to the extreme summit of such apparatus.'

4. That the 'Ventilator' shall be able to be contained within a square of definite dimensions.

5. That the length of pipe attached to each such 'Ventilator' shall be the same in every case.

6. That all such sizes and dimensions shall be agreed upon prior to competing.

Hoping that the above will draw forth the opinions of some of your correspondents.—We are, your obedient servants,

SHARP & Co.

11 Holborn Circus, London, E.C.

VENTILATION.

During the past few years science has made most rapid strides in all branches, and on this account we are able to live more luxuriously and healthily than did our forefathers. We may even go so far as to say that some diseases have been stamped out entirely, black-death and plague being never heard of in the British Isles, and other

pulmonary and cutaneous diseases do not commit the ravages they used to.

The question which naturally presents itself is, what is the cause of this? The answer is briefly this, that the medical and engineering professions have joined hands and act in unison with the one laudable object in view—to save their fellow creatures and increase the strength of their country by preventing and removing the causes which have given and still give rise to disease, and the one great proof of this is to be seen in the International Health Exhibition.

A vast number of diseases, such as typhus, erysipelas, small-pox, &c., arise from overcrowding, filth, and bad ventilation. I am not so presumptuous or so trusting in man's strength to even hint that we can entirely prevent such diseases, for that ever is and must be in God's hands alone; but what I do say is this, that it has been put in our power to guard against them, and it is our duty to do so.

I have made it my special business for some time past to carefully study the question of ventilation, with a view to discover the best means of ventilating all buildings, and I may certainly be allowed to state, without fear of contradiction, that very few of the means applied in any way attain their object. It is not ventilating a chamber to simply create a draught, nor is it ventilating a chamber to simply cut holes in the walls and place gratings over them; but the secret of ventilating is to allow the pure air in without inconvenience to the inhabitants, and to abstract the foul or vitiated air at as regular a rate as possible, without noise and without unsightly objects in the building.

For ventilating a chamber the principal facts to be ascertained are the entire feet of air contained in the chamber, the maximum number of people likely to be in the chamber at one time, allowing for each person at the rate of at least 3,000 cubic feet of air per hour, taking into consideration the important question of how the chamber is to be lighted when gas consumes the entire amount of 8 cubic feet, 1 lb. of oil from 140 to 160 cubic feet per hour, candles six to the pound about 170 per hour.

In proof of what I have above stated, allow me to quote what Dr. Guy says:—'In the twelfth century there were fifteen widespread epidemics and many famines. In the thirteenth century there were twenty epidemics and nineteen famines, and in the fourteenth century there were eight epidemics and more famines.' Dr. Guy then goes on to say that 'these epidemics, it should be remembered, were not local outbreaks appearing only here and there, but they spread so far and wide that each and all of them were regarded as visitations of national disaster.'

In tracing epidemics it will be seen that black-death in 1348 swept away one-fourth of the entire population, and the same style of illness was scourging the whole of Europe, carried partly, no doubt, by infection, but caused principally, there is every reason to believe, by the sanitary condition then existing. The sweating sickness, which was dispelled by the great fire of 1666, and which, it appears, originated in this country, was proved to arise from bad ventilation. Now since the change of sanitation, which took place about the beginning of the eighteenth century, what great results can be shown? Simply that black-death, sweating sickness, and plague have been removed from the bills of mortality.

Again, Mr. John Howard reduced the ravaging effects of jail typhus fever by introducing ventilation.

Surely with such startling facts before one it is not too much to ask architects, engineers, and builders to make special provision in their plans and estimates for so necessary a part of their work, and to ask medical men and the public generally to see that all public and private buildings are properly ventilated.

I may add, in conclusion, that it has been my special interest and pleasure to carefully examine all the systems of ventilation exhibited at the International Health Exhibition, and the only one which I can honestly recommend, and that I do very strongly, is the one exhibited by Messrs.

Aldous & Son. Their exhaust is the only one which is really sealed from downward draught, and which acts thoroughly at all variations of wind and temperature, and it is, moreover, impossible for it to get out of order, the whole of it being stationary and self-acting.

WARREN HENRY DRAKE,
1 Westminster Chambers.

HOUSING OF THE WORKING CLASSES.

*'How best to help the slender store,
How mend the dwellings of the poor?'*

LIVERPOOL LABOURERS' DWELLINGS COMPANY, LIMITED.—At the thirteenth annual meeting of the Liverpool Labourers' Dwellings Company, Limited, the report presented by the directors, which was unanimously adopted, stated that the demand for cottages had fallen off, and many cottages having remained empty, the rents were considerably reduced. Although this step was taken the directors were glad to state that the gross rents received only showed a diminution of about 10%, as compared with last year, and the cottages had been better tenanted. The expenditure showed a decrease of about 30% as compared with last year. The net profit on the year's working was 515/4s. 6d., and adding to this sum the amount carried forward from last year, 111/4s. 4d., there was a sum of 526/8s. 10d. available for dividend. The directors recommended that a sum of 496/4s. be applied to the payment of a dividend at the rate of 3 per cent. per annum, and that the balance of 30/4s. 4d. be carried forward to next year.

PRISON SITES FOR INDUSTRIAL DWELLINGS.—The suggestion which has been made by Mr. W. McCallagh Torrens, M.P., a member of the Royal Commission on the Housing of the Working Classes, that the Government should remove into the suburbs the prisons and lunatic asylums which now occupy so large a space in densely populated districts of central London—the vacated sites being utilised for artisans' and labourers' dwellings—has been received with much favour in North London, particularly in Clerkenwell and St. Luke's. In the former parish, surrounded by a crowded population of poor people, stands the House of Detention, which is admittedly ill-adapted and inadequate for the purposes it has to serve, while Coldbath Fields House of Correction, a little further away, covers eight or nine acres of ground, in a locality where industrial dwellings are most needed. The St. Luke's Asylum, in Old Street, a very grim and prison-like edifice, occupies a vast space in a district where the want of decent accommodation for the working classes is greatly felt. The patients in this institution would, it is said, no doubt be benefited by being removed into the country. With the rapid growth of the metropolis the prisons and asylum mentioned—originally situate in green fields—are now almost in the very centre of London, and in the midst of a crowded population of poor folks to whom it is of the utmost advantage to live near the scenes of their daily toil.

WORKMEN'S DWELLINGS.—A company called the National Conservative Industrial Dwellings Association (Limited), with an authorised capital of 999,000, has just been incorporated for the purpose of constructing sanitary dwellings for artisans, labourers, and others, and of enabling working men to become the owners of their own houses, cottages, or agricultural allotments by a system of payments extending over a term of years. The association, which will own freehold property only, and be conducted on sound and strict business lines, will not confine its operations to crowded neighbourhoods. Besides erecting improved sanitary dwellings in populous districts, it will construct cottage residences at low rents in the suburbs, and as a special feature will, by making

arrangements with the railway companies, comprise the cost of the tenants' season tickets in the rents. In country districts the association proposes to build cottages for agricultural labourers, and to acquire land for subdivision into allotments. In order to identify the association with the working classes, and to give them a share in its control, a large amount of industrial stock will be issued exclusively to working men. It is claimed that the association will offer an absolutely safe security for the investment of small savings, and thus foster self-help among artisans and labourers as much by improvement in their personal and domestic surroundings as by placing within their reach the means and the incentives for the cultivation of provident habits. It may be added that the association is promoted by gentlemen closely connected with the Conservative party as an earnest of the real and practical interest taken by them in the social wellbeing of the working classes.

THE HOMES OF THE JEWISH POOR.—The Sanitary Inspector to the Jewish Board of Guardians has recently visited 1,151 houses inhabited by Jews in the district of Whitechapel, and gives the following as the result of his inspection:—Found perfect, 911; entirely remedied, 71; partially so, 54; requiring remedy, 115. 'The Inspector,' the report goes on to say, 'in choosing the districts and houses to visit, has sought to inspect first those in the most crowded districts in which the Jewish poor generally live, and those houses apparently in the worst condition. It is satisfactory to find that of 1,151 houses visited, only 240 required to be put in a more sanitary condition. The 71 houses in which entire remedy has been procured have often been improved by drawing the attention of the landlords to their unsanitary state; but in some cases the parish authorities had to be asked to insist on the remedy. Of the 115 cases where remedy is still required about one-half are under the inspector's supervision, and some remedy may be expected without delay.' It was explained that the word 'perfect' as applying to 911 houses, meant that they were up to the average condition of houses not requiring repair.

PARKS AND OPEN SPACES.

*The law condemns both man and woman
Who steals the goose from off the common;
But lets the greater felon loose,
Who steals the common from the goose.*

THE Mayor of Bradford has opened the Bradford Moor Recreation Grounds, which have been dedicated to the use of the public by the Town Council. An estate consisting of forty-eight acres of moorland having been purchased at a cost of 10,000*l.* by the Corporation, an excellent site, comprising one-third of the whole, has been laid out as pleasure-grounds, 8,000*l.* being spent in the ornamentation of the land, the formation of lawns for tennis, football, cricket, and other outdoor games.

OWING to the efforts of the Metropolitan Public Garden, Boulevard, and Playground Association the enclosure in another London square has been thrown open for the use and recreation of the public. Following the example of the Duke of Westminster in the case of Ebury Square, Pimlico, the Marquis of Northampton has leased to the association named, of which Lord Brabazon is president, about an acre and a half of garden ground in Canonbury Square, Islington, at a merely peppercorn rental. The society has supplied it with seats, and they will provide a caretaker. Lady Brabazon formally declared the garden of Canonbury Square open to the public in the presence of a numerous and representative assemblage, including Lord Brabazon, the Rev. D. Wilson, vicar of Islington, the Rev. Dr. Allon, Mr. Ernest Hart, Dr. Septimus Gibbon, medical officer of health for the Holborn district, and many others.

TREE PLANTING IN LONDON.—Trees are about to be planted on each side of the improved portion of Gray's Inn Road, and it is expected that the planting will be continued by the St. Pancras Vestry on the part of the thoroughfare which is under their jurisdiction as far as King's Cross. The contemplated improvement will convert a rather dingy road into a handsome promenade, especially in the fine wide portion of Gray's Inn Road, stretching from Holborn Town Hall to High Holborn.

SANITARY JOTTINGS.

SANITARY.

THE report of the medical officer of health of Sandown, Isle of Wight, for the quarter ending June 30, shows one of the lowest death-rates ever known in the south of England. Out of a population of close upon 4,000 inhabitants only three deaths had occurred.

The Reddish Local Board having obtained an order from the Local Government Board suspending the Rivers Pollution Act, 1876, have given instructions to Mr. R. Vawser, C.E., Manchester, to prepare a plan for the complete sewerage of the district.

The Tyne Port Sanitary Authority have provided a new floating hospital, which is moored near Jarrow Slakes. It was formerly a Dutch galliot, and the deck space now contains two wards—one for eight beds, and the other for four beds. The cabin has been fitted up for the accommodation of a nurse, and the hold has been utilised as a store room. The work has been satisfactorily carried out under the superintendence of Mr. J. H. Taylor, the Chief Inspector of the Authority. The offer of the *Plaver* by the Admiralty for the above purpose has been declined.

Professor De Chaumont, Medical Officer of the Privy Council, has recently been on an official tour of inspection to the chief towns on the Tyne, and has expressed his satisfaction at the arrangements made to prevent the importation of cholera from abroad and the spread of infectious disease generally.

The death-rate of the borough of Gateshead for the past month again exhibits the excessive average of 30 in the 1,000 per annum. This high mortality is still engaging the earnest attention of the Corporation.

Small-pox has recently been very prevalent in the city and county of Durham, though, according to the latest returns, it shows signs of abatement.

Scarlet fever is still the most prevalent of zymotic diseases at Newcastle-on-Tyne.

The Ellis Lever Prize of £500 for an approved safety lamp has not been awarded, the adjudicators—Thomas Burt, M.P., Sir Frederick A. Abel, Profs. Gryll Adams and S. P. Thompson—not being able to discover a lamp, amongst the 108 brought before them, which fulfilled the conditions required.

Dr. Robert Koch has been appointed Director of the new Hygienic Institute attached to the University of Berlin.

NOTICES OF MEETINGS.

THE PLUMBERS' CONFERENCE AT THE HEALTH EXHIBITION.

At a representative meeting of gentlemen interested in the art and trade of plumbing held at the Guildhall on the 16th ult., to take into consideration the desirability of action being taken, by which the status of the trade might be advanced, and the interest of the public protected from evil arising from bad work and bad workmen, Mr. George Shaw, C.C. (master of the Plumbers' Company), was elected to the chair.

The chairman, in addressing the meeting, said they had met there as members of the public as well as plumbers, and they wanted protection for themselves and families against the evils arising from bad plumbing. The protection of the public and the protection of the interests of the craft and trade of plumbing

were virtually synonymous terms. The foundation of the Plumbers' Company rested on this sound basis. The 'ordnance' of King Edward III., dated 1365, provided 'That no one of the trade of plumbers shall meddle with works touching such trade, except by assent of the best and most skilled men in the said trade; testifying that he knows how well and lawfully to do his work; that so the said trade may not be scandalised, or the commonalty damaged and deceived by folks who do not know their trade.' The 'ordnance' further provided for good material being used. There was no trade or craft, continued Mr. Shaw, which so directly affected the public health as that of plumbers. The object of the proposed conference would be to give practical expression to the 'ordnance' of the Plumbers' Company. That company comprised among its members men who, like himself, had worked with their own hands in every branch of the plumbing trade, and who had acquired their experience both as men and as masters. In addition, the Plumbers' Company had members who were professional men, and men whose social position enabled and entitled them to support the credit of the body and to advance its usefulness. It was therefore in as good a state of efficiency now as at any previous time in its long history to perform its appropriate and legitimate functions for the fair protection of the public, as well as for those who honestly followed the trade and craft of plumbers.

Resolutions were passed requesting the Plumbers' Company to communicate with the National Health Society, the Sanitary Institute, and otherwise to arrange for the conference of metropolitan and provincial plumbers to be held at the Heath Exhibition from Oct. 15 to 20. A committee was appointed to arrange and carry out the objects of the meeting.

The following syllabus of subjects was decided upon for discussion at the conference:—1. The technical instruction of plumbers. 2. Apprenticeship, the duration and condition of indentures suited to the present state of the plumbing trade and to the modern system of technical instruction. 3. The establishment of metropolitan and provincial boards of examiners of plumbing work. 4. The registration of journeymen plumbers. 5. The suitability of materials used in plumbing, and particularly of those materials recently introduced as substitutes for lead. 6. The desirability of fixing upon a system by which uniformity in the quality of material used in plumbing may be insured. 7. The formation of district associations of plumbers to investigate and secure, as far as practicable, corrections of evils and abuses arising in connection with the trade. 8. A general and executive committee to be formed for the purpose of receiving reports from district associations of plumbers and others with a view to the preparation of a general report by the Plumbers' Company, to form the basis of an appeal to Parliament for necessary amendments and extensions of the law relating to plumbers' work under the Building and Health Acts, and otherwise.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

SESSION, 1884.

T. ORME DUDFIELD, M.D., President.

The first meeting of the session will be held on Friday, October 17, at 7.30 P.M. The minutes of the last meeting will be read. The council will present a report. Mr. Hugh Stott, medical officer of health of Friern Barnett (proposed by Dr. J. Northcote Vinen and Mr. Shirley Murphy) will be balloted for as a member of the society. Dr. Frederick East, of 4 Clapton Square, E. (proposed Dr. G. P. Bate and Mr. Shirley Murphy) will be balloted for as an associate of the society. The president will deliver an inaugural address. The president, in the name of the society, will present to Dr. J. Northcote Vinen, vice-president, a copy of a resolution adopted at their last meeting of the society, and testifying to their high appreciation of Dr. Vinen's services as honorary secretary to the society during a period of twenty-one years.

SHIRLEY F. MURPHY, 153 Camden Road, NW.

C. E. SAUNDERS, M.D., 21 Lower Seymour Street, W.
Hon. Secretaries.

APPOINTMENTS UNDER THE PUBLIC HEALTH ACT.

MEDICAL OFFICERS OF HEALTH.

AITCHISON, Dr. Henry, has been appointed Medical Officer of Health for the WallSEND District, in succession to his father.
ALLISON, John, L.F.P.S.Glasg., L.S.A.Lond., has been re-appointed Medical Officer of Health for the Brighthelm Urban Sanitary District, at £50 for one year.
ASHWORTH, James Henry, L.R.C.P. Edin., and L.M., F.F.P.S. Glasg., L.S.A.Lond., has been re-appointed Medical Officer of Health for the No. 1 Division of the Halstead Rural Sanitary District, at £44 for one year.
BARTON, John Arondel, M.B.C.M. Univ. Glasg., has been re-appointed Medical Officer of Health for the St. George Urban Sanitary District, at £50 for one year.
BELL, Peter Gordon, L.R.C.P. Edin., L.R.C.S. Edin., has been re-appointed Medical Officer of Health for the No. 1 Division of the Burton-upon-Trent Rural Sanitary District, at £50 for one year.
BOSWELL, John Irvine, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Medical Officer of Health for the Faversham Urban Sanitary District till Lady Day 1886, at the rate of £45 per annum, and for the Faversham Port Sanitary District till Lady Day 1886, at the rate of £15 per annum, *vice* Atthill, resigned.
BROMLEY, John Bourne, M.R.C.S. Eng., L.S.A.Lond., has been re-appointed Medical Officer of Health for the No. 2 Division of the Halstead Rural Sanitary District, at £60 for one year.

CLARK, William Wake, M.D. Univ. Edin., M.R.C.S. F. Lond., has been re-appointed Medical Officer of Health for the Wellingborough Urban Sanitary District, at £30 per annum.
DANIEL, Edwin, L.R.C.P. Edin., L.F.P.S. Glasg., and been re-appointed Medical Officer of Health for the St. Sanitary District, at £25, for one year.

DAVIDSON, Patrick Moir, L.R.C.P. Edin., and L.M. Glasg., has been re-appointed Medical Officer of Health for the Congleton Urban Sanitary District, at £50 per annum.

DAVIES, John Hopkyn, M.R.C.S. Eng., L.S.A.Lond., has been appointed Medical Officer of Health for the Margam Urban Sanitary District, at £30 per annum.

ELLIOTT, George Hurlstone, M.R.C.S. Eng., L.S.A.Lond., has been re-appointed Medical Officer of Health for the Chic Sanitary District, at £55, for one year.

FISHER, Luke, M.D. Univ. St. And., M.R.C.S. Eng., I has been re-appointed Medical Officer of Health for the Urban Sanitary District, at £55, for the year ending next.

FORSYTH, Robert Adam, M.D., has been re-appointed Medical Officer of Health for the Drighlington Urban Sanitary District, at £18 for one year.

GARMAN, Walter Chancellor, M.B., C.M. Univ. Edin., has been appointed Medical Officer of Health for the Wedne Sanitary District, at £84 per annum, *vice* John Cook, L.R.C.P. Lond., M.R.C.S. Eng., resigned.

HARDWICKE, William Wright, M.R.C.P. Edin., and L.M. Edin., has been appointed Medical Officer of Health for the Harwich Urban and Port Sanitary Districts, at £45 *vice* Kinsey-Morgan, resigned.

HASWELL, Narcis Richard, M.R.C.S. Eng., L.S.A.Lond., has been re-appointed Medical Officer of Health for the H. Sanitary District, for six months ending Lady-day, at rate of £100 per annum.

HEPWORTH, William, M.R.C.S. Eng., has been re-appointed Medical Officer of Health for the Veadon Urban Sanitary District, at £15 for one year.

HOOPER, Alfred, M.R.C.S. Eng., L.S.A.Lond., has been appointed Medical Officer of Health for the No. 2 Division of the Trent Rural Sanitary District, at £50 for one year.

HOSGOOD, William, M.B., C.M., Univ. Edin., has been appointed Medical Officer of Health for the Amersham Rural Sanitary District, at £50, for one year.

MILLET, George Bown, L.R.C.P. Edin., M.R.C.S. F. Lond., has been re-appointed Medical Officer of Health for the Fenice Urban Sanitary District, at £40 for the Sept. 29, 1885.

MORTON, Dr. John, has been re-appointed Medical Officer of Health for the Guildford Urban Sanitary District, at £42 per annum, for three years.

NORMAN, John William, L.R.C.P. Edin., has been appointed Medical Officer of Health for the Ross Rural Sanitary District, at £60 per annum, for three years.

VIANT, Henry, L.R.C.P. Edin., M.R.C.S. Eng., and L. Lond., has been appointed Medical Officer of Health for the New Forest Rural Sanitary District, at £100 per annum, for three years.

WHITTON, John, L.R.C.P. Edin., M.R.C.S. Eng., I has been re-appointed Medical Officer of Health for the Bierley Urban Sanitary District, at £70 for one year.

SURVEYORS, CLERKS TO GUARDIANS, INSPECTORS OF NUISANCES, &c.

BARRS, Mr. Thomas, has been re-appointed Inspector of Nuisances for the Bromyard Rural Sanitary District, at £60 per annum.
BRECHING, Mr. Charles Edward, Banker, has been appointed Treasurer to the newly-formed Bexhill Local Board Sanitary Authority.

BETTS, Mr. Charles Lineker, has been appointed Collector of District Rates to the Melton Mowbray Local Board Sanitary Authority, at £40 per annum, *vice* Cobley.

BOWRING, Mr. John, has been elected a Member of the T. Local Board and Urban Sanitary Authority, *vice* ceased.

BREEZE, Mr. John, has been re-appointed Surveyor of Nuisances to the Wellington (Salop) Rural Sanitary District, at £140 per annum.

BROWNE, Mr. Rowland, Solicitor, has been appointed Clerk to the Carmarthen Guardians at £85 per annum, and Clerk to the Rural Sanitary Authority, the Assessment Committee, School Attendance Committee, at such salary as may be from time to time, and fees as Superintendent Registrar &c., and Returning Officer, *vice* Phillips, deceased.

BURGES, Mr. Isaac, has been appointed Inspector of Nuisances for the East Hampstead Rural Sanitary District, at £70 per annum, and Surveyor for the Sandhurst division, at £20 per annum, for the Brackhill Division, at £10 per annum.

BURGOYNE, Mr. James, has been appointed Collector to the Local Board and Urban Sanitary Authority, at 20 per annum, *vice* Hooke, resigned.

CHAPMAN, Mr. John James, has been re-appointed Inspector of Nuisances for the Stone Urban Sanitary District, at £50 per annum. (He is also Surveyor at £50 per annum.)

CLAUGHTON, Mr. Joseph, has been elected a Member of the North Local Board and Urban Sanitary Authority, *vice* resigned.

CLAYTON, Mr. Edward, has been re-appointed Inspector of Nuisances for the Mansfield Urban Sanitary District, at £30 per annum, until May 2, 1885.

COLES, Mr. Robert, has been elected a Member of the Sidmouth Local Board and Urban Sanitary Authority, *vice* Harvey, deceased.

DOVE, Mr. Walter, has been elected a Member of the Claines Local Board and Urban Sanitary Authority, *vice* Rowe, resigned.

FRITH, Mr. John, has been re-appointed Inspector of Nuisances for the North Bierley Urban Sanitary District, Yorkshire, at £30 for one year.

GOLDSTONE, Mr. F. B. T., Manager of the Newport Branch of the Capital and Counties Bank, has been appointed Treasurer to the Town Council and Urban Sanitary Authority of Newport, I.W., *vice* Grant, resigned.

HANHAM, Mr. Joseph, has been appointed a Collector to the Corporation and Urban Sanitary of Sunderland, *vice* Bradley, resigned.

HIFFITH, Mr. D., Manager of the National Provincial Bank, Denbigh, has been appointed Treasurer to the Town Council and Urban Sanitary Authority of Denbigh, *vice* Pritchard, resigned.

HARCOCK, Captain, has been elected a Member of the Board of Hove Improvement Commissioners and Urban Sanitary Authority, for the Brunswick Ward, *vice* Baron de Teissier, deceased.

HASTIE, Mr. Arthur Hepburn, Solicitor, has been appointed Clerk to the newly-formed East Grinstead Local Board and Urban Sanitary Authority.

HEDGES, Mr. Francis Edward, Solicitor, has been appointed Town Clerk and Clerk to the Urban Sanitary Authority of Wallingford, at £55 per annum, *vice* Mr. Charles Hedges (his father), resigned.

HOLYOAK, Mr. Henry D., has been elected a Member of the Ashbourne Local Board and Urban Sanitary Authority, *vice* Lucas, resigned.

JEFFERIES, Mr. William, has been elected Chairman of the Bromsgrove Board of Improvement Commissioners and Urban Sanitary Authority for the ensuing year.

JERSON, Mr. —, of Stockport, has been appointed Inspector of Nuisances for the Market Harborough Rural Sanitary District, at £110, and Surveyor at £20 per annum, from year to year, *vice* Wills, appointed Surveyor and Inspector of Nuisances to the Wavertree Local Board and Urban Sanitary Authority.

JOYCE, Mr. Thomas John, has been re-appointed an Inspector of Nuisances for the Helston Rural Sanitary District, for six months ending Lady Day next, at the rate of 20 guineas per annum.

LEWIS, Mr. Lewis, has been elected a Member of the Board of Hove Improvement Commissioners and Urban Sanitary Authority, for the Stanford Ward.

LOCAS, Mr. Alfred, has been elected a Member of the Board of Hove Improvement Commissioners and Urban Sanitary Authority, for the Stanford Ward.

MARDAN, Mr. James, has been appointed Treasurer to the newly-formed Margam Local Board and Urban Sanitary Authority.

MATCHEAN, Mr. J., the late Surveyor, has been appointed Consulting Surveyor to the Town Council and Urban Sanitary Authority of Great Grimsby, at £100 per annum.

MILNER, Mr. Thomas George, has been appointed Accountant to the Town Council and Urban Sanitary Authority of Kingston-upon-Hull, at £200 per annum, *vice* Thelwall, appointed Treasurer.

MOLYNEUX, Mr. Herbert, has been elected a Member of the Milverton Local Board and Urban Sanitary Authority, *vice* Bell, resigned.

MONKS, Mr. Aquila, has been appointed Clerk to the Stapleton Local Board and Urban Sanitary Authority, at £50 per annum, *vice* Rawle.

NANKIVELL, Mr. W. H., has been re-appointed Inspector of Nuisances for the East Dereham Urban Sanitary District, at £50 for one year.

NORMAN, Mr. Joseph C., has been elected a member of the Hadleigh Local Board and Urban Sanitary Authority, *vice* Cook, deceased.

PARSONS, Mr. Joseph, has been re-appointed an Inspector of Nuisances for the Helston Rural Sanitary District, for six months ending Lady-day next, at the rate of £30 per annum.

PERRY, Mr. William, has been appointed Surveyor to the Town Council and Urban Sanitary Authority of Stourbridge, at £40 per annum, *vice* Taylor, resigned.

PHILLIPS, Mr. Alfred, has been appointed Surveyor and Inspector of Nuisances to the Ely Local Board and Urban Sanitary Authority, at £120 per annum, *vice* Bowen, resigned.

ULLINGBEE, Mr. George Bonamy, has been re-appointed Inspector of Nuisances for the Chichester Rural Sanitary District, at £33s. for one year.

RITCHARD, Mr. Hugh Foulkes, Branch Manager of the National Provincial Bank of England, has been appointed Treasurer to the Corporation and Urban Sanitary Authority of Carmarthen, *vice* Thomas, deceased.

ATER, Mr. William, has been appointed Surveyor and Inspector of Nuisances to the Lillington Local Board and Urban Sanitary Authority, at £77 per annum, *vice* Bradford, resigned.

FRITH, Mr. Emmett, has been re-appointed Inspector of Nuisances for the Hedden Bridge Urban Sanitary District, at £70 per annum for two years.

RYE, Mr. Robert, has been elected a Member for the Eccles Ward of the Barton, Eccles, Winton, and Monton Local Board and Urban Sanitary Authority, *vice* Waddington, deceased.

VEST, Mr. Stephen, has been re-appointed Inspector of Nuisances for the St. George Urban Sanitary District, at £50 for one year.

ALBERT, Mr. C. R. M., M.P., has been elected Chairman of the newly-formed Margam Local Board and Urban Sanitary Authority, Glamorganshire.

THELWALL, Mr. John, has been appointed Treasurer to the Town Council and Urban Sanitary Authority of Kingston-upon-Hull, at £400 per annum, *vice* Witty, deceased.

THOMAS, Mr. William, has been appointed Surveyor and Inspector of Nuisances to the newly-formed Margam Local Board and Urban Sanitary Authority, Glamorganshire, at £20 and £30 per annum.

THOMAS, Mr. William Edmond, has been re-appointed Surveyor and Inspector of Nuisances to the Neath Rural Sanitary Authority, at £160 for one year.

THORPE, Mr. Joseph Lloyd, has been appointed Collector to the Elland Local Board and Urban Sanitary Authority, at £75 per annum, *vice* Iredale, resigned.

TIPPEN, Mr. Thomas, has been re-appointed Surveyor, Inspector of Nuisances, Water Works Manager, and Collector to the Wigton Local Board and Urban Sanitary Authority, at £95 per annum.

WARD, Mr. Amos, has been elected a Member of the Pudsey Local Board and Urban Sanitary Authority, *vice* Tunnicliffe, resigned.

WHITESIDE, Mr. Thomas, has been re-appointed Inspector of Nuisances for the Lytham Urban Sanitary District, at £50 per annum.

VACANCIES.

MEDICAL OFFICER OF HEALTH for the Nottingham Urban Sanitary District. Application to the Town Clerk.

MEDICAL OFFICER OF HEALTH for the East Grinstead Urban Sanitary District. Application to A. H. Hastie, Clerk to the Authority.

MEDICAL OFFICER OF HEALTH for the Gainsborough Rural Sanitary District.

MEDICAL OFFICER OF HEALTH for the Stafford Urban Sanitary District. Application to the Town Clerk.

MEDICAL OFFICER OF HEALTH for the Bridgnorth Urban Sanitary District. Application to the Town Clerk.

CLERK to the Hemel Hempstead Guardians and Rural Sanitary Authority. Application to the Chairman.

CLERK to the Margam Local Board and Urban Sanitary Authority. Application to the Chairman, Margam, near Neath.

SURVEYOR to the Town Council and Urban Sanitary Authority of Great Grimsby: £200 per annum, with a clerk, and permission to take pupils. Application, 18th inst., to W. Grange, Town Clerk.

INSPECTOR OF NUISANCES and **SURVEYOR** for the Bangor and Beaumaris Rural Sanitary District: £130 and £20 per annum for three years. Application, 30th inst., to John Thomas, Clerk to the Authority, Bangor.

SURVEYOR and **INSPECTOR OF NUISANCES** to the East Grinstead Local Board and Urban Sanitary Authority: £100 per annum. Application to A. H. Hastie, Clerk.

SURVEYOR to the Shirley and Freemantle Local Board and Urban Sanitary Authority. Application to the Clerk.

SURVEYOR to the Loughborough Local Board and Urban Sanitary Authority. Application to the Clerk.

SURVEYOR to the Kenilworth Local Board and Urban Sanitary Authority. Application to the Clerk.

SURVEYOR, INSPECTOR OF NUISANCES, and COLLECTOR to the Consett Local Board and Urban Sanitary Authority. Application to Thomas William Welford, jun., Clerk.

SURVEYOR to the Lytham Improvement Commissioners and Urban Sanitary Authority. Application to W. Blackhurst, Clerk.

INSPECTOR OF NUISANCES for the Longton Urban Sanitary District: £100 per annum. Application, 27th inst., to George Hulme Hawley, Town Clerk.

INSPECTOR OF NUISANCES for the Skidmore Urban Sanitary District. Application to John William Skidmore, Clerk to the Authority.

COLLECTOR to the Margam Local Board and Urban Sanitary Authority. Application to the Chairman.

LOCAL INTELLIGENCE.

ABERGAVENNY IMPROVEMENT COMMISSIONERS AND URBAN SANITARY AUTHORITY.—At the annual election the following were elected for the ensuing three years, viz.: Messrs. H. J. Cadogan with 148 votes, T. Delafeld 131, *John Morgan, 130, and *Captain W. Williams 127. (*Retiring Commissioners re-elected.)

BROMSGROVE IMPROVEMENT COMMISSIONERS AND URBAN SANITARY AUTHORITY.—The following have been elected Members of the Board for the ensuing three years:—Messrs. Joseph Amphlett, Thomas Newbold, Joseph Weaver, Robert A. Hall, and Thomas Billingham.

CHESHAM LOCAL BOARD AND URBAN SANITARY AUTHORITY.—The first election of members has resulted in the return of Messrs. William Lowndes by 650 votes, Edward Simmons by 511, David Hawkins 476, George Webb 473, Alfred Judge 464, Edwin Birch 450, Frank Lovel Lasenby 429, Thomas Nash 418, and Charles Herbert 414.

The Camborne Local Board and Urban Sanitary Authority have increased the salary of Mr. Thomas Negus, the Surveyor and Inspector of Nuisances, to £107 10s. per annum.

Mr. John Gannan, Chairman of the Cavan Town Commissioners and Urban Sanitary Authority, has been placed on the Commission of Peace for the County Cavan.

The Dawlish Local Board and Urban Sanitary Authority have increased the salary of Mr. John Sumner Whidborne, the Clerk, from £50 to £70 per annum.

The Flint Gas and Water Company have offered their undertakings to the Town Council and Urban Sanitary Authority at a price to be settled by arbitration, and the offer has been accepted.

The Town Council and Urban Sanitary Authority of Cheltenham have increased the salary of the Surveyor to £525 per annum, upon his taking over the duties of the Highway Inspector, who has resigned.

The Bristol Town Council and Urban Sanitary Authority have voted £300 to Mr. Frederick Ashmead, the Surveyor, for his extra services in connection with the building of the new Redminster Bridge; and increased the salary of the Assistant Surveyor, from £250 to £300 per annum.

The West Hartlepool Improvement Commissioners and Urban Sanitary Authority have awarded £115 to Mr. W. Procter, Surveyor, Inspector of Nuisances, and Collector to the Seaton Carew Local Board and Urban Sanitary Authority, as compensation for his loss of emolument, upon the Seaton Carew District being dissolved and added to West Hartlepool.

The Mansfield Guardians and Rural Sanitary Authority have increased the salary of Mr. G. H. Hibbert, the Clerk, £50 per annum, 'on the distinct understanding that it is to cover all assistance employed by him, and that no further increase be asked for during his term of office.'

The Hemel Hempstead Guardians and Rural Sanitary Authority at their last meeting, upon the report of the death of Mr. Charles Ehret Grover, their Clerk, passed the following resolution unanimously:—'That the deep and earnest sympathy and regret of this Board at the loss of so valuable a public officer, who from the formation of the Union has so faithfully and ably discharged the duties of his office, be recorded, and that a copy of this resolution be sent to the family.'

The Pudsey Local Board and Urban Sanitary Authority have, with the sanction of the Local Government Board, reduced the salary of Mr. Joseph Town, the Inspector of Nuisances, from £60 to £67 per annum.

The Chertsey Rural Sanitary Authority have been invested with the powers, rights, &c., of an Urban Sanitary Authority, under sect. 45 of 'The Public Health Act,' as to the temporary deposit of dust, ashes, and rubbish, within the contributory place of Chertsey.

Although the Local Government Board have settled the boundaries of a place, and appointed a summoning officer to take the necessary steps for constituting a Local Government district at Chertsey, it is very doubtful if it will be carried out, for at a meeting of the pro Local Board Committee, Mr. G. Boyce, the chairman, said in the face of the expression of feeling shown at a recent public meeting, he did not think it would be advisable to go on with the matter further, although he felt certain the time would come, and that shortly, when the inhabitants would be sorry that the Board was not formed. It was also explained that the committee had succeeded with the Local Government Board in their petition, and that the district carved out by them had been adopted in its entirety. It was also noticeable that since the formation of the committee the existing authorities had done a great deal more for the town. It was determined not to dissolve the committee, but to let the question remain in abeyance.

The Denton and Haughton Local Government Districts were amalgamated on Monday, September 29, in accordance with the order of the Local Government Board. The new district is to be called the 'Denton and Haughton,' and the Board is to consist of fifteen members.

The first election of a Board of nine members for the newly-formed Menai Bridge Local Government District will take place on Dec. 6.

The recently-formed East Grinstead Local Board and Urban Sanitary Authority, at their last meeting, discussed the order of retirement of the members; and upon the suggestion of the Rev. C. W. Payne Crawford, the chairman, the names were written on separate pieces of paper, placed in a hat and drawn, with the following result:—Messrs. Padwick, Crawford, Charlwood, and Smeed, to retire at the end of the first year, Messrs. Southey, Gatty, Foster, and Tooth, at the end of the second year, and Messrs. Taylor, Absalom, Stenning, and Bailey, at the end of the third year.

The Windsor Urban Sanitary Authority have increased the salary of their Medical Officer of Health from £40 to £60 a year.

NOTES AND QUERIES.

Having for some time back been in the receipt of Queries appertaining strictly to sanitary work, and which it would be easy to answer, without having to refer our correspondent to competent professional advisers, we have opened a column in which to register such Queries and Replies thereto as can fairly be expected from us; and our subscribers and readers are invited to make such use of this column as will tend to benefit themselves and the community. Both Queries and Replies will, however, be subjected, if unnecessarily long, to a strict curtailment.

130. IRON HOT WATER CISTERNS.

1. How long will a properly galvanised iron hot water cistern last? Why does this kind of cistern soon rust inside and the rust appear outside?

2. Is there any objection to a copper cistern tinned inside (for hot water)?

3. Can you recommend any other kind of cistern for a hot water system?

W. J. S.

[1. It is impossible to say how long a galvanised iron cistern will last. A great deal depends upon the proper cleansing after galvanising from the acid used in the process, which very often cannot

be eradicated from the crevices around rivets, where it attacks the metal and eats it into holes, sometimes from the outer, and sometimes from the inner side.

2. A copper-tinned cistern is decidedly the best for a hot-water system, and is not open to any more objection than a copper tea kettle.

3. There is not anything better than copper.—Ed.]

131. WINTER HEALTH RESORTS.

Now that the Continent is practically closed in respect to Winter Health Resorts, I want some particulars of English sea-coast and inland places to which I can send patients requiring mild climates. Do you know of any small manual containing such information?

M.O.H.

[M.O.H. will find the details he desires of the soil, climate, and meteorological characteristics of Hastings and St. Leonards, Eastbourne, Worthing, Ventnor, Bournemouth, Torquay, Pezance, Llandudno, Leamington, Cheltenham, and Bath, all of which are suitable for the purpose indicated, in 'Where to take a Holiday': the Holiday Number of the LONDON MEDICAL RECORD, published by Smith, Elder, & Co., 15 Waterloo Place, S.W. Price 1s.]

INTERNATIONAL HEALTH EXHIBITION.

TO THE PARLIAMENTARY COMMITTEE OF THE MAIN SEWERAGE BOARD OF THE LOWER THAMES VALLEY.

494 South Annexe, Oct. 9, 1884.

Gentlemen,—By a report published in the *Times* of this morning it would appear that you have had referred to you two schemes for the removal or treatment of sewage now discharged from your district into the Thames.

One scheme emanates from Sir Joseph Bazalgette and the other from Mr. W. Shields. The first is said to be merely an elongation of the existing main drainage system, which is well known too frequently to utilise the several outlets to the river. The other the *Times* describes as being based on the conveyance of the sewage of the whole district to a spot at Isleworth within the district, and its chemical purification upon land to be purchased by agreement for that purpose. Now surely this is a revival of the principle rejected last session by the Select Committee of the House of Commons.

In a handbook published under the authority of the Executive Committee here, an eminent authority thus describes a sewer which is made to convey more than a pure effluent:—

'Truly, a sewer is an unlovely thing to think upon, with its stench, gases, and fungi, bred of putrefying liquids seething in the dark. . . . Directly solid refuse is diluted with water its money value vanishes, a though its theoretical manurial value remains.'

Both of the above systems involve enormous cost, the first especially, and experience has taught ratepayers that neither can be remunerative; above all, it is notorious that neither can give adequate relief. The authority above quoted goes on to say:—'It may, I think, in relation to this question of sewage, be laid down as an axiom, the greater the detail the greater the ease, the greater the security to health, and the greater the profit.' Before being biased by the advocates of either of the two schemes in question, it is to be hoped that attention will first be given to the 'Cloacina' principle exhibited here, as it fairly encompasses all the requirements published in the handbook referred to, under the title of 'Our Duty in Regard to Health.' A grave responsibility devolves upon you in giving a decision as to the course to be taken for the relief of dwellers in the Lower Thames Valley, and consequent upon the overflow above described, the dwellers in the Upper Thames district are also concerned in your decision; and the report of the Government Engineer (Mr. Harrison) has sufficiently described the pitiable condition of the river taking the aforesaid overflow.

Till the end of this month the 'Cloacina' models will be here on view, and they show that by 'prompt interception, deodorisation, and filtration in detail,' a pure effluent would alone pass into the river, and the valuable residuum contained in the receiving tanks (after these operations) may be removed in an inodorous condition.

Subways conveying telegraph wires beneath the pavement would best serve towns exercising this mode of treatment, but till local authorities find the courage to form subways, and save the tearing up of their streets upon every little gas and water service operation, till then the devotion of part of the coal cellar of each dwelling would suffice for the 'Cloacina' process, and it should be borne in mind that in no way does it involve the old cesspool nuisance, simply because, independent of the application of cheap and ready disinfectants, the continuity of the sewer or tank with the dwelling is entirely cut off, and the cellars or subway could be ventilated as the sewers now are by gutter gully holes; in suburban districts a pit deep enough to give a fall and to hold a removable galvanised iron tank, possessing a simple arrangement for ventilation, and an escapement for a filtered effluent would at once provide relief for the greater part of the Lower Thames Valley, and should inquiries of the attendant here not be sufficiently explanatory to any member or members of your Board, further particulars may be obtained at the Sanitary Works Office, 12 Buckingham Street, Charing Cross.—I am, gentlemen, yours obediently,

D. NICOLL.
P.S.—An article copied from the *Lancet*, and republished in the *Morning Post* on the 10th inst., should interest all sanitarians. In point of fact, it is as a brief would be, if held by counsel in defence of the 'Cloacina' system.—[ADVT.]

ORIGINAL PAPERS.

RESSURE IN ELEMENTARY SCHOOLS.

By EDITH LUPTON.

Bringing the subject of over-pressure in schools, and the very varying and contradictory opinions held by writers and speakers on the subject, seems to me that before the subject can be treated it will be necessary to come to some definite understanding than at present exists of the term over-pressure really means, and to include, and also what methods are to be used of receiving evidence on the matter. And I should wish to deprecate what I should call the method, by which it is assumed that all the present working of our Education is either foes to educational progress, or are motives of personal interest. A common and must be assumed before any profitable can take place. As to what over-pressure is, and that most inquiries on the matter begin with the somewhat ghoulish question, 'Are any dead?' and when, happily, there are no returns, it is considered that the subject is closed off, and that no further investigation is

being of the subject myself, I shall beg to be taken much wider ground, and to include in 'over-pressure' any physical or mental harm to any child as a consequence of the Education Acts. I fear that I do take some of my readers with me in this, but it is not generally acknowledged that there is any duty towards delicate children. The report of a well-known School Board on over-pressure, which has attracted some attention much quoted, was based on the assumption of over-pressure, to be well founded, as occurred in a previously *entirely healthy* child. B. W. Richardson, I think, says that such our present state of civilisation does not require, therefore, perhaps, scarcely necessary to the most happy paucity of 'cases' was the he inquiry. For myself, I feel the gravest when I hear it said the authorities 'cannot children are delicate;' that the 'system' be lowered to 'suit the requirements of the child and that, in fact, 'killing is no murder,' if a poor little victim has had a diseased or constitution. Such a doctrine introduced into any life would produce rather startling and it is certainly opposed to our general of action. We acknowledge the duty of infant life, however feeble, and the State in numerous and increasing asylums, a place of support for adults who, by reason of mental weakness, are unfitted to take in the world; but, by a curious moral school-boy has no place in this chain of care, and should he be sickly or feeble, he is a soldier in an ill-disciplined army, to drop ranks and die by the wayside. And this is extraordinary, as the school-boy is at a age, when mind and body are peculiarly to external influences, and when skilled and mental training may produce the happy results on his whole future life. Seeds of disease

may be eradicated, feeble brains strengthened, the blind may see and the deaf hear, and the State may be furnished with able-bodied citizens instead of useless paupers. But the State has not yet recognised a duty in this respect, and of course it may be said that the State, in undertaking to give an elementary education, does not undertake any responsibility as to the health of the children, and that the parents must still be responsible for their physical well-being; but the fact is that successive codes have year by year stretched such increasingly greedy hands over the children that they are now almost entirely taken from the care of their parents, and the legal powers, either actual or assumed, of the educational authorities are so great that parents are simply not allowed to protect their children.

I do not think I am speaking too strongly when I say that a gross and ignorant tyranny has in the name of education risen up amongst us, and that it is time the nation opened its eyes to what is going on.

I am aware that to the various charges brought against the Education Department by parents, doctors, school-managers, and teachers, of causing in various ways injury to the children's health, Her Majesty's inspectors bring in most cases a simple denial. I would not for a moment charge these gentlemen with saying anything which they did not firmly believe to be the truth; but I would ask, Are they in a position to judge? Have they any means of really acquainting themselves with the actual facts concerning the lives and health of the children whom they inspect? To my mind, when these gentlemen say that they have seen no cases of over-pressure, it is as if a man on one side of a brick wall should say that he had not witnessed an occurrence which took place on the other side, and if he should then proceed to generalise from that that nothing did take place, I doubt if his evidence could be very good in law. And here I would remark that I think that in any investigation of the subject of over-pressure, evidence should be received in a judicial manner, and that the same weight should be attached to it as it would have in a court of law; that the letters H.M.I. should not be supposed to confer on their possessor medical knowledge out-weighting that of trained and experienced doctors, and that we shall have no more of such pretended investigation of cases by the Education Department as occurred a few months ago when the evidence of the doctor who had seen and attended the dying child, was considered to have been entirely disproved by an inspector who went down after the child's death and saw her tombstone.

Of the manner in which Dr. Crichton-Browne's evidence has been received by the Government, it seems to me that one can only say it was scandalous, and it has certainly not met with the approval of the nation. No doubt the instructions laid down for inspectors as to the care they are to exercise in supervising the health and general well-being of the children are most seductive, but they prove too much and fail by very excess of merit; for they show that there is evidently no relation between human capacity and the duties imposed by the department on its inspectors. When one has read over and carefully considered the list of all the inspector must do, the time he has to do it in, and the limited opportunities that will be at his command of obtaining information, one is tempted to write at the end: 'which is absurd, therefore —.' But to

proceed to examples. One of our most important schools in Bradford, consisting of four departments, boys, girls, infants, and half-timers (mixed), was examined at the end of September. Four days were allotted for the inspection, one day to each department, and as there were, speaking roughly, three hundred children in each, and reckoning the day at five hours, exactly one minute was left for the personal inspection of each child. Out of that time had to be taken the time required for inspecting log-book, school premises, sanitary arrangements, teachers and pupil teachers. The children had to be examined in reading, writing, arithmetic, singing, sewing, English, geography, elementary science, history, drawing, and algebra. The Infant Department in facts about animals, coal, gas, salt, form, colour, food, plants, clothing, rain, frost, &c., &c.; modelling, geometrical drawing, weaving, plaiting, drill. Then there was the 'merit grant' in all the schools, 'organisation and discipline,' 'intelligence in instruction,' 'behaviour of children,' inspection of the 'exemption schedule' and its authentication 'by attendance officer,' 'children who are present but exempted from examination.' The inspector was here required by his instructions not to accept the statement of the managers, but to inquire for himself whether there was 'adequate reason for withholding;' and was specially warned not to allow too many little fish to escape through his meshes, for his instructions say 'in ordinary conditions such exceptions should be *very few*.' How pleasant that a Government can by a few strokes of its pen thus regulate the health of its people!

Then not only had the inspector to observe all the things just enumerated on the day of inspection, but he had to satisfy himself that in the daily management of the school the children were being brought up in 'habits of punctuality,' 'good manners and language,' 'cleanliness and neatness,' 'cheerful obedience to duty,' 'consideration and respect for others,' 'honour and truthfulness in word and act,' and not only that regard had been paid in classifying them 'to their health, age, and mental capacity;' but—*Credat Judæus!*—that the 'dull and delicate had not been' at any time during the preceding year unduly pressed. And all this in five hours! May we not then feel a little sceptical when we find inspectors sending in medical reports as well? Three hundred children reported on mentally, morally, and medically at the rate of a minute a piece! while I am assured on eminent authority that a medical man can only thoroughly examine from twenty-five to thirty patients in a whole day (and that without regard generally to their minds and morals)!

Then, again, inspectors do not see the schools as they are. The day of inspection is known proximately during the whole year, and the exact day for several weeks previously. The children come with Sunday clothes, clean hands and face and collars—which last are known specially to appeal to masculine sensibilities. I do not believe an inspector ever considered a child morally or physically deficient who was sanctified by a bit of starched linen round his neck.

Close class rooms are shut up, floors are washed, desks polished, windows opened, children adjured with passionate earnestness 'to be good for the inspector.' All are excited, nervous, and eager, looking anxiously for weather-signals in his (the in-

spector's) face, hoping that he will be in an amiable mood or not be obliged 'to catch a train.' No one would dream of revealing to him any defect that could be concealed. He does not come as a friend, as a counsellor, who from his wider experience might give valued advice, judicious blame, and well-deserved praise. No, he comes as an enemy to represent the distrust of the Government for its teachers and people; he comes to deprive teachers of their hard-earned salaries, often of their very subsistence, and, dearer than all, of their reputation; he comes to take away from managers the money which they absolutely require for the carrying on of their schools, and to deny to the people of the town that proportion of their hard earnings which they have voted shall be spent on the education of their children. Can we, then, suppose that gentlemen visiting the schools under the circumstances just described are in a position to give satisfactory evidence as to the working of these schools? No; eminent as are the talents of many, and fruitful of good and pleasure as their visits might be under a more rational system, I do not think that the people of the country will feel that the question of over-pressure can be settled by their reports. For myself, I consider that there is the most pressing and earnest need of proper medical inspection of school-children, and also of a proper revision of our educational system, by those in the country who understand best in what proper educational and physical development consists. I consider that not only are delicate children treated with what is really at times barbarous cruelty, but that the vitality of strong children is often seriously depressed by antiquated and ignorant modes of instruction. That there are many people in the country who could give us the most admirable advice I am well convinced. The present Government did not invent education, and the inheritors of a literature second only in splendour and power to that of the Greeks, and the possessors of a present scientific eminence second to none, need not be the slaves of any governmental system. It is freedom to carry out our best knowledge in the education of our children that we want. As for the necessity of medical inspection, will it be easily credited that there are many poor parents who have to choose between letting a child whom they know to be ill attend school, or being fined or imprisoned? and though a well-to-do man can pay a fine, a poor man will have to go to prison. The following cases are well attested.

Magistrate: 'Why do you not send your little girl to school?'—Father: 'Because she has got rheumatic fever, and nobody shall make me send her.' Fined 10s. 6d.

A mother attends in answer to a summons, which states that her girl, aged 13, does not go to school. Mother says the girl is ailing, and going to school makes her sick and ill. She does not know what to do, as she is too poor to pay a doctor. Has lost six girls, and fears to lose this one too.

Father ill, out of work; mother, father, and four children live on 11s. a week, earned by mother and eldest boy. Case remanded for School Board officials to get doctor's certificate. Officials do not get certificate, because it is not 'in the Code.' Child taken by myself to see doctor, who says she is suffering from premonitory symptoms of brain-fever, and gives certificate that she must not go to school for six months. If I had not accidentally heard of the case the child would now be forced to go

al, as the father fears much being sent to

met with a severe accident to his head, and clever at his lessons before, became afterwards stupid. Father sent the boy, who could go to school only half-days, and let him hawk the other half. Is told he will be sum-

He takes the boy to the doctor under the care he had been after the accident. Doctor thinks could be better for the boy under the circumstances than walking about, and gives certificate the boy must only attend school half-days. Father asks why the boy is not attending school. Doctor: 'I have a doctor's certificate.' Officer: 'This man, your worship, is obstinate, and defies us!' Magistrate: 'Must be put a stop to: you are fined 2s. 6d., if your boy is to go to school full time.' This brings to the kindness of Mr. Stanley Leighton, who brought to the attention of the Education Department in the House of Commons.

Another case. Child ill from St. Vitus's Dance. Doctor sends doctor's certificate, stating that the child must not attend school. Officer presses for a decision. Magistrate: 'What reason can you give for pressing for a fine in the face of this certificate?' Officer: 'I consider the child to be well.' Magistrate: 'You do not understand: what medical advice have you that the child is fit to go to school?' Officer: 'I do not consider any medical advice needed: I consider the child to be well.' Magistrate: 'I consider this case is dismissed.'

Another case a poor woman, whose child had for many years been an out-patient at various hospitals for affections of the eyes and ears, was unable to go to school very occasionally, and was called by the officer and asked why the child was not at school. The mother said the child was unwell, and was then a patient at the Infirmary. The officer said, 'I'll examine the child.' He turned her to the light, looked at the child, and said, 'I think she's quite well: you'll be satisfied.' And summoned the woman who was fined, and fined, for hospitals do not give certificates, but for another kind appeal to the Magistrate by Mr. Leighton. This child has, I think, had her delicacy much increased by imprisonment at school. She was not able to go to school on account of ill health till she was 10. At that age the mother thought her much better, and that it would be very good for her to go to school, as she could get discipline and companionship. The doctor under whose care she then was gave a certificate, stating that she was in a state of health to attend school, and, with great reluctance, the child was admitted, the mistress being unwilling to receive a child who could not read. After her admission I called several times to look after her, and succeeded in impressing on the school authorities the fact of her delicacy, and she was not to be beaten if she did not understand. Her then improvement in health and intelligence showed how beneficial school schooling may be to the most delicate child. Unfortunately, however, the child improved so much that the mistress declared (I was present at the time and did not hear of the matter) that she considered the child quite well, and should

'work her up' for the examination; and this delicate child of 7 (who was then a patient at the Eye and Ear Hospital) was kept in school from 9 o'clock in the morning till 1, and from 2 till 5 or 5.30 every afternoon, was beaten and scolded if she did not understand or hear, and in a few months she had become pale, thin, and miserable, screaming in her sleep, and her eyes a mass of inflammation. She has never been able to go to school since, and will very likely have to thank the Board School system for permanent injury to her health. I think myself it is simply monstrous that young and feeble children should be allowed to be the sport of such ignorance as I have described; and this child is only one of thousands who are suffering more or less from the same gross violation of the laws of health. I do not think there can be a better example than this case of the benefits of education when the education is for the child, and the evils of it when it is for the parent.

Some time ago in the Burnley district a little girl died suddenly. At the inquest a verdict was returned that she 'died from attending school while in an unfit state of health.' The parents gave evidence that they knew the child to be unwell (I think her lungs were affected), but that the officer called so often and threatened them with a summons if she did not attend, that they were frightened, and let her go. Of course a Government inquiry was held, and blame was given—to whom? to the officer for his ignorant tyranny? No; to the parents, for having done as he told them!

To leave now exceptional cases, let us inquire how the children as a body are treated according to our system. Great efforts are made by many authorities to get parents to send their children to school at three years of age, and in cases where mothers go out to work it is often necessary to send the younger children somewhere. These children are, as might be expected, generally mere babies, some of them cannot even talk, and common sense and common knowledge knows that at that age it is the physical development that should be most attended to.

Our Board School authorities, however, know nothing of the kind; reading, writing, and arithmetic are with them the Alpha and Omega of all knowledge and virtue. These children are put on benches, often in a half-lighted, close little class-room, and compelled to sit upright and perfectly still for 5½ hours a day, with the exception of one quarter of an hour's run in the playground morning and afternoon. Occasionally a few toys are introduced, but the babies often do not even get the benefit of exercise in the large school-room, which the other infants enjoy, but sit hour after hour staring with unknowing eyes at an alphabet on a board, a teacher standing midway with a long pointer, with which she now points out the letter A and now raps the head of a baby who has not learnt that heads were not meant to be turned. There is no exercise for the lungs, for the arms, for the legs, and no rests for the poor little backs. What the babies think about all day I do not know, but a solemn vacuity seems for the most part to have taken possession of their souls.

Perhaps there is not much active harm done in these schools, and it is more the absence of benefit which might be derived from pleasant playgrounds, floors to roll about on, and games and laughter that is to be deplored. But when the serious business of compulsion begins at five, it is most deplorable that there is not a medical inspection of the children, so

case the law was also violated by the officials, as there is no compulsion on a child to attend school after the age of thirteen.

that none may be set to work who are not fit for it. It is then that the half imbecile, scrofulous, rickety children should be weeded out, and should be placed under special medical care, and a course of study suited to their capacities. There is no more painful or condemnatory sight than these poor, obviously feeble children being 'screwed up' by slaps, scoldings, and keepings in to prevent their diminishing the amount of grant earned, suffering themselves and the cause of suffering to their teachers.

I am aware that Art. 8 of the New Code is supposed by the Department and the inspectors to have remedied these evils. 'Dullards are easily protected, and are intended to be protected, by the New Code,' says one sanguine inspector, but practically it does not do more than touch the evil complained of. It has already brought other evil consequences in its train, and has caused so much indignation among parents that if carried out as it has hitherto been I think it will be the last straw which will break down the patience of the long-suffering English ratepayer and parent. Under this clause children are still trained experimentally. No medical opinion is obtained, no dictates even of common sense are heard; the unfortunate child is turned over to the only less unfortunate teacher, and it is only when he has been experimented upon for a year, and has shown that no physical or mental torture can extract any 'results' from him, that he is at the very last 'exempted from examination,' with this result, that while he has suffered from 'over-pressure' during the whole year, he is debarred at the last from the possible chances of a 'pass' at the examination, which might have set him free to follow some manual employment, for which his poor dull faculties might be fitted, and which would bring in for himself and his family some much-needed help. But to return now to the actual school life of the children. In many respects the curriculum of our infant schools is much more satisfactory than that in our other departments. The subjects chosen have an agreeable variety, and I often meet with infants who seem intelligent and interested in their work, who take pride in telling what they have learnt, and in showing how well they can read.

The great defect in these schools is in the want of recognition of how beneficial and necessary activity is to children, and how painful to all, and how impossible to some, is the enforced school quietude, and far too frequently death is the consequence of the hasty blows bestowed to punish children for what is scarcely the crime of being 'wick.'* But as the children go to the upper schools and advance in the standards, this intelligent cheerfulness ceases, the long hours of ceaseless poring over books begins to tell upon them, the subjects taught become more and more removed from any connection with their lives or interests. Astronomy, Physical Geography, History, and Literature, taught merely from the pages of the driest, most unlitrary, most unscientific, and most uneducating of class books, what can they do to stimulate the minds and intelligence of the children? They receive no ideas from them. The mental exercise for the most part consists of committing pages to memory, of which they do not understand half the words. I came upon a class of little girls of about ten years of age one day, reading a chapter of feudal history.

The page was crammed with such words as 'feoffment,' and other obsolete legal phrases, describing the terms of the feudal tenure, which I would have taken a very Blackstone or Hallam to explain; and this we call 'educating' the children and it is for such knowledge as this that inspectors almost tearfully implore that the law may be made stricter so that the children may be compelled to remain in school until they have learnt all that the (the inspectors) can teach them. May Heaven preserve them from such a fate! and may it send us instead hearts to feel for their poor aching heads, their sick hearts, and their bewildered brains. As remains of some of that vast inheritance that has come down to us from our Puritan forefathers we still believe in the educational advantages of making children miserable. Would that we could learn to believe in the inestimable advantages of happiness as an educator, and in kindness and consideration as the best means of developing the children's minds. Meantime we have in our school consumptive children, epileptic children, children afflicted with all the evils that flesh, and especially the flesh of poor half-fed, half-clothed children, heir to (and it must be borne in mind that the children of the poor have not by any means the same physical and nervous strength as the children of well-to-do parents), and all must be bound by absolutely the same system, and a system it is in many cases of Draconian severity. Poverty receives daily physical punishment when the father is out of work and cannot send money for school fees or books, and even to cough is an offence punished with the cane. I have recently been investigating the case of a little girl who has become epileptic through being caned for a cough she could not control, and on my obtaining a medical certificate to save her if possible from future suffering, the matter was merely treated with ridicule, it being considered too ridiculous to suppose that an epileptic child should not be caned, and yet the treatment of epileptic children is a very serious matter, as they are very largely increasing in number in our schools. But of all sources of over-pressure there is none so great as the long school hours now imposed on the children. An average of six hours a day for five days a week for eight years, from five to thirteen, spent in poring over books, to say nothing of constant overtime work, often daily of several hours, and of the fact that in some districts the actual school hours are considerably longer than those I have named (for the Education Department, while strictly fixing a minimum limit for school hours, has adopted no maximum), gives, I think, an amount of attempted brain-work which in itself proves the existence of over-pressure. I know of several well-to-do parents who have wished their daughters to remain at school till fourteen, so that they might receive a good education, who have taken them away as soon as the law allowed, finding the excessive work imposed was injuring their health. Lord Stanley of Alderley called the attention of the Government to this most important point in the House of Lords last session, but the Department of course could not see any occasion for interference, preferring to trust as usual 'that somehow good will be the final goal of ill,' but there is no doubt that the maximum number of school hours should be most strictly and definitely settled. It certainly seems anomalous that while the employer of a full-grown woman may be heavily fined for over-

* A 'wick' child means in Yorkshire a vigorous, active, lively child.

hour's overtime work, that in the name of on children may be kept at work any number of hours. Such physical torture is never imposed on children of educated people. An eminent man has said 'we were never intended to spend a part of our lives in looking at little black and white paper'; and let people think of the easy school hours of young children, of the healthy variety of work taught them, their careful physical training, their long joyous months at the seaside or in the country, and compare these things with the ceaseless work of the children of the poor, who are compelled. The evil effects of constant sedentary work in a confined position on the system are well known to need repetition by me, but it is remembered that the children of the poor have limited capacity and preference for manual work, so that in their case the confinement is less irksome. Many ingenious seats are contrived to prevent children suffering from a stooping posture, but, if I may express an opinion, I do not think children ought ever to sit over their books for as long as to need such appliances, and much as I am a German systems of education, I think they have made a grave mistake in requiring such long hours of work, and especially for English children would I see the great need of plenty of physical activity. Practical energy always acknowledged by none in Germany to be the great characteristic of the English nation? then why should we in educating children of the nation run counter to the English national characteristic? We talk much about education with a big 'E'; but is education a quality and a thing apart from all other conditions? is it not rather an adaptation of means to ends, and is not that human being the best fitted for the life he will lead?

Now in England it is scarcely possible to discuss the question calmly, owing to the desperate situation which has arisen that the Germans and French in some mysterious manner, going to take all our manufactures away from us, and it is arming the intellects of our children, as we were our volunteers twenty years ago, to repel a French invasion, that we shall continue to do so. Indeed, I think that this present scare is due to that in the person of 'Boney' frightened our fathers so many years ago. Meantime our legislators take hasty trips abroad and come back with scraps of continental educational systems hung about them, somewhat in the fashion of a savage adorns his person with beads from other nations, and when any remonstrances are made of the desirability of our adopting the same, we are told by our rulers, with alarm in their eyes and ears, that we are losing all our trade; unless we make the most exertions we shall soon have no trade. Of course if our present Educational Code is our national armament it perhaps should not be subjected to much educational or medical criticism. I would remind our rulers that people are educated by having a portion of a continent system rudely grafted on the top of their life, than the savage before referred to is when he dons a chimney-pot hat or waistcoat emblematic of his adhesion to civilisation and

and last, but not least, the personal wants and individuality of each little child. The *Times*, whose educational views are certainly a little 'mixed,' after insisting one day on the merits of our present system gave a day or two after an article in praise of the methods of education pursued by the Christian Brothers. With true liberality the *Times* will evidently give all systems a place in its Pantheon. The system of the Christian Brothers is, I may say, the exact opposite of ours. The individual capacity of each child is specially studied. No books are used in teaching young children, and those as young as ten or even eight mingle manual labour with their intellectual activities. This is what we want in England: half-time schools, where girls, beside moderate intellectual attainments, may learn cooking, sewing, house work, dairy work, and other industrial employments; where boys may be instructed in those trades they will afterwards have to follow, and learn to take an intelligent interest in and have an intelligent knowledge of their work. A man who is only going to be a weaver will drive his machine all the better for understanding the principles on which it is constructed, and a girl who marries at sixteen will surely be a better wife for knowing something of the duties she undertakes. The deadly languor and hatred of schooling which has no practical connection with either their past or their future lives, and which increases on children with every year of their school life, will pass away, and we shall have children coming to school full of eagerness to learn what will be of practical value to them.

Of the evils that are brought about by want of food I will not speak, because they are obvious; nor will I enter into the question of the injury done by the pass examinations for labour certificates, as that, though important, is more a local perhaps than a national question; and of the evils of payment by results so much has been said and so eloquently that I will only allude to it, but I believe it to be the prime cause of all the evils complained of in physical, mental, and last, but not least, moral deterioration. The children are taken out of the hands of their parents, teachers, fellow townsmen, and all who might be supposed to take, or who do take, an interest in them, and are tied to the wheels of a Government system to revolve as the State decrees. It is true that I heard the noble President of the Education Department lately say how very easy that system was, but that made me think of some of the wonderful machines to which our century has given birth, and in which, by means of a little handle that a child can turn, an almost irresistible machine is set in motion. It is no doubt easy for the President to sit in his chair and sign the necessary documents, but he does not see the enormous flywheels whirling in the distant parts of the country which start into life at the strokes of his pen.

Of course, I know it may be said that most of the evils complained of are in the power of the school managers to remedy if only instead of trying to earn money they would think of the welfare of the children; but the fact is money is necessary to managers to enable them to carry on their schools. We have long heard of the wicked teachers who actually wish to have money to live upon, and now we are beginning to hear of the equally wicked school managers who wish for money to enable them to carry on their schools. The mistake is that

wish to educate we must first consider wants, class wants, local economic wants,

the Government regards the money it gives as a reward. It is not so; it is the necessary money voted by the nation for the education of its children, and of which all schools require their share. It is childish to tell us that we must make our schools efficient and never mind whether we get money to support them or not; and when inspectors actually tell us that many of our schools would be more efficient if they earned less Government grant, and that to make them efficient we must not try for grant, I consider that the system is self-condemned by the mouths of its own supporters. Independence of the Government grant is all we want, and the law will then allow us to take our proper place as school managers; but as long as we have to earn money we must earn it how we can, and we have now to earn it by being managers in little more than name, and by paying a slavish obedience to the slightest regulation of a department which thinks that from a single office at Whitehall it is capable of regulating the individual life of each one of the millions of school children under its dominion. That it cannot do this successfully is, I think, becoming increasingly evident, and I hope most earnestly that the public attention which is being at present bestowed on the subject will result in the establishment of an educational system more suited to the needs of a great and progressive nation and to the physical and mental wants of each individual child.

SMALL POX IN DURHAM.—In response to a requisition to the mayor a public meeting of the inhabitants of the City of Durham has been held to consider the best steps to be taken to prevent the further spread of small-pox now so prevalent in that city. There was a numerous attendance of the leading gentlemen of the city and university under the presidency of the mayor Dr. Lake, Dean of Durham, in moving the first resolution, urged the necessity of promptly providing a temporary hospital or other place for the proper isolation of patients, in which he was supported by other speakers, the resolution being carried unanimously. On the motion of Archdeacon Watkins it was resolved 'that the clergy, all ministers of religion, and medical men residing in the city act as a committee to provide immediately trained nurses for the poor now suffering from small-pox.' At the monthly meeting of the Durham Urban Authority held on the 5th instant, the Finance and General Purposes Committee recommended the authority to apply to the county justices for the use of old militia stores as a hospital for infectious diseases; as also to the Race Committee for the use of the Grand Stand for that purpose, as well as to the Dean and Chapter for land to be used also for checking the progress of the disease. Two memorials were read praying the authority to take prompt measures to stay the spread of the disease and to provide a hospital at once. The town clerk read the report of the medical officer of health (Dr. Barron), wherein it appears that officer has repeatedly urged upon the authority the necessity of providing a hospital ever since the first appearance of the disease in that city, and the necessity had daily become more urgent. Fifteen deaths from the disease had occurred during the month of October. It was interfering with trade and causing much misery. Mr. Barnes complained of the culpable manner in which persons affected with the disease exposed themselves in the streets. It was suggested that schools be closed during the prevalence of the epidemic. It was announced that the justices were willing to grant the use of the militia barracks for a hospital, and they have since been utilised for that purpose. Canon Boddy has taken the initiative and secured the services of trained nurses to visit the sick at their homes and to provide necessary comforts.

THE HOUSING OF THE POOR.*

By JOHN PRICE.

Resident-Director of the Newcastle Industrial Dwellings.

AFTER so much has been said and written on the important subject of housing the poor, I fear it is somewhat difficult to avoid travelling to some extent over well-trodden ground; yet I trust that the experience of one who has been intimately associated with the working classes for a very long period, and who has also for the past fourteen years been resident manager of a large block of industrial dwellings, may not be found entirely devoid of interest. A person who occupies such a position obviously enjoys greater facilities for practically studying the question than those who are not afforded such opportunities.

The poor may be divided into two great sections, the deserving and the undeserving. Whilst the former are entitled to our warmest sympathy and support, as being placed in their unfortunate position through no fault of their own; the latter are poor, and probably always will be poor, on account of their own vicious habits, which seem as difficult to get rid of as for the Ethiopian to change his skin. Poverty is caused quite as much by the waste of money as by the want of it. If the two sections could always be kept apart, the great problem of the hour would be much nearer a solution than it appears to be at present. We find the victims of vice and misfortune so mingled together in the slums of our large towns that sanitary and other conveniences, which are much appreciated by the well-disposed, are continually neutralised or destroyed by people who are equally regardless of their own and neighbours' health and comfort as they are of their landlord's pocket.

It will be generally found that it is this dirty, destructive, and non-rent-paying class that are most blatant over their self-inflicted grievances, and impose on unwary philanthropists by their plausible fictions. If these people were put into mansions of faultless construction and spotless cleanliness, they would, if allowed, soon reduce their new homes to the condition of their former hovels: squalid nurseries of filth, disease, and vice. It certainly seems unreasonable to be continually harassing the landlords of property inhabited by such people to keep it in thorough repair, when they know the impossibility of the task from bitter experience; and that whatever repairs they do will be speedily undone by malicious and unprofitable tenants. No greater hallucination can exist than to imagine that property inhabited by a disreputable class of tenants is really such an El Dorado as is sometimes represented by writers, who are guided more by sentiment than a desire to learn the truth. The fact is, such property seldom proves remunerative, as the occupants not only cause the unfortunate landlord endless trouble and expense in repairs, but resort to every known artifice to avoid paying rent at all. It is scarcely necessary to observe that, as a rule, their household requisites are distinguished by their scantiness and portable character, so that, if desirable, a sudden change of residence can be accomplished with remarkable celerity. I have known cases where the owners of tenemented property in Newcastle have actually given it away rather than be further subjected to the annoyance and expense which it entailed.

* Read at the Newcastle Diocesan Conference, Oct. 30, 1884.

It may naturally be asked, Why do landlords or their agents admit such undesirable tenants into their property? In answer to which question it may be stated that no sane person would do so knowingly; but in spite of all the precautions taken they get admission most frequently by practising gross deception.

In seeking admission such applicants prove themselves adepts at simulation, and occasionally present themselves with borrowed clothes on their backs, a well-filled rent-book and forged character in their hands; this trick, along with a plausible tale of their antecedents, sometimes succeeds in throwing the landlord or agent off his guard; as he cannot always spare time to verify credentials, he may trust to appearances and is thus deceived. It sometimes happens that a respectable-looking relative of the family is employed to take a room or house for the intended occupants, when their own appearance is not considered prepossessing. Once in possession they can cause the landlord considerable trouble and loss, before they can be ejected in legal form, which is a dilatory and expensive process, and is only resorted to under compulsion. From the constant frauds to which landlords and their agents are subject, they have now become much more wary than they were formerly, and disreputable parties now find it a more difficult task to impose on them. It would be absurd to deny that bad landlords do exist, but in the majority of cases it will be found that it is bad tenants that make bad landlords.

From long personal observation, I have no hesitation in expressing my opinion, which is but the echo of other persons of equal experience, that the primary cause of much of the poverty and wretchedness to be met with in the slums of Newcastle, as well as of other large towns, arises from a constant craving for drink by the inhabitants, which destroys all regard for the best affections of human nature, and for everything calculated to make a happy home.

The numerous temperance agencies that have been established in Newcastle, have undoubtedly done much good amongst the male population of the working class; but it is a lamentable fact that drinking amongst women is alarmingly on the increase.

As home is the birthplace of all that is good or evil in man, no effort should be spared to preserve the purity of the domestic hearth; the best of all reforms begin at home and cannot be accomplished without the voluntary aid of wives, mothers, and daughters; it is important that we enlist them under the right banner. Here the clergy can render efficient aid.

But, from whatever cause these nurseries of disease and vice have sprung up in our midst, it is a most suicidal policy to allow them to remain, impregnating the atmosphere, physical and moral, with their foulness; they should be uprooted at all hazards, as their injurious effects are seldom confined to the locality where they originate. Infectious disease spurns geographical boundaries and class distinctions, and although generated in wretched hovels, often finds its way by subtle means to the mansions of the rich, selecting its victims with startling impartiality. We therefore cannot afford to ignore its existence; self-interest, if no higher consideration, should prompt us to take energetic steps for its removal. The longer we suffer the cancer to grow, with apathetic indifference, the more dangerous it will become, and the more difficult to remove. The evil must, therefore, be

faced boldly if we desire an efficient cure, but how is this desirable result to be accomplished?

In my humble opinion, the initiative rests with the sanitary authorities, whose staff should be augmented if required, so as to enable them to make an efficient inspection of all houses periodically, so that they may detect any defects of construction as well as the existence of any nuisance detrimental to the public health. It is desirable that vigorous efforts be made to find out and punish the real offenders, who create the nuisances, and not, as is often the case now, to visit the shortcomings of bad tenants upon the head of their unfortunate landlord who is frequently made to pay dearly for the removal of nuisances of whose existence he was probably ignorant till pointed out to him by the authorities.

Malicious tenants, who were in arrears of rent, have been known to stop up drains and water-closets, or do other wilful damage, and then coolly report the existence of the nuisance to the inspector, with the object of gratifying their petty spite at their landlord's expense. Sanitary officers thus sometimes unwittingly become the catspaw of bad tenants, and owners of tenemented property more particularly complain bitterly of this annoyance, which would soon abate if the real offenders were reached and punished; depraved minds only practise virtue under compulsion. We have seen the excellent results of the police supervision of common lodging-houses; the system should be extended in a certain degree to tenemented dwellings. The Corporation of Newcastle seem desirous of carrying out this view, and have recently passed a set of by-laws under the 90th section of the Public Health Act, which are not altogether of a satisfactory character; whilst some of the clauses justly affect dirty tenants, by other clauses landlords will be subject to much unnecessary trouble and expense, through the default of their tenants. These obnoxious clauses have created much dissatisfaction amongst owners of tenemented property, which possibly may lead to some desirable modification of them. Otherwise landlords may prefer, as the lesser of two evils, to shut up their property rather than be subject to further irritating annoyance and loss. Thus the injudicious exercise of stringent powers may intensify the difficulty, by leading to the continued eviction of the most troublesome class, who must find accommodation somewhere, and at somebody's expense, even if it be the ratepayers. We cannot expect landlords to ruin themselves for the benefit of worthless tenants. It will be obvious that the death-rate of a locality is often quite as dependent on the habits of the residents, as upon the construction of their habitations, and therefore the death-rate of a place cannot always be regarded as an infallible test of its normal healthiness. And here I may observe that the Church can render valuable aid by instructing her clergy to strive all in their power to inculcate the necessity of habits of temperance and cleanliness amongst their parishioners; if this could be accomplished, they would find their future work much more pleasant. It has been well said that cleanliness is next to godliness.

Having thus referred to the people and causes which make our slums a disgrace to us, and thwart in no small degree the best efforts of the clergy, sanitarians, and philanthropists, we will now take a glance at the more agreeable side of the picture, and consider the wants of the really deserving poor—unfortunately a numerous class, whom it is unjust

to punish or neglect for the faults of their less deserving brethren.

In going through the slums of our large towns we sometimes come across a humble dwelling which arrests our attention by the contrast it affords to its surroundings—a clean, bright spot or oasis in a wilderness of filth, whose occupants, despite their misfortunes and scanty furniture, have not forgotten the lessons of cleanliness engrafted into them during their earlier and happier days: this is the class that wins our sympathy. Compelled by necessity, and not from inclination, to inhabit places whose only attraction is their low rental, as best suited to their limited resources, and to herd amongst those whose antecedents and habits are very different to their own, they evidently endeavour to put the best face on their misfortune, and show us that even our slums, with their manifold defects, can be made to present a much cleaner and healthier appearance than they generally do. The principal cause of poverty amongst the deserving class is the want of employment, now unhappily so prevalent, and sickness, contingencies which cannot be avoided by the keenest human foresight.

It should be clearly apparent that the majority of the labouring poor cannot afford at any time to pay any proportionally large amount out of their slender and uncertain earnings in the shape of rent. There are hundreds of men in Newcastle who in the best of times cannot earn more than 20s. per week to keep themselves and their families; at present, many would probably be thankful for a fraction of that sum. Much as these poor people may appreciate healthy homes and sanitary conveniences, they are often far beyond their reach, and they are compelled to subjugate their desires to their means. Two shillings per week is the utmost that most unskilled labourers can afford to pay out of their weekly earnings for their dwellings; and many cannot pay even that sum with a due regard to the necessities of their families. Unfortunately no one has yet been able to show us any practical plan by which suitable dwellings could be erected on a sound commercial basis, at a cheap rate, so as to let at this low rental, and yet produce a satisfactory return as an investment, though many efforts have been made. The excellent work of Miss Octavia Hill and her coadjutors may be said to come the nearest to the desired end; but it must be remembered that her plan of transforming old houses into improved dwellings is only available to a limited extent, where opportunities occur, so that her laudable and economical system can only be regarded as but a partial remedy for housing the multitudinous poor, who require to be dealt with on a much larger scale.

The authorities of several of our large towns have shown their sincere anxiety to grapple with this important question in a practical manner. It is now thirty-two years since the Corporation of London took the matter in hand, and before the passing of Sir R. Cross's Act in 1875 they had provided accommodation for 1,800 persons. They have just erected a block in Petticoat Square for about 1,000 persons, at an estimated cost of 68,000*l*. It is not necessary to refer at length to the many blocks of model dwellings which have been erected in London during recent years, for although the majority of them have proved a gratifying success in a commercial sense, their erection does not seem to have benefited the real poor to any appreciable extent, not even excepting the magnificent blocks belonging to the Peabody Trust.

One of the most exhaustive and able paper has yet appeared on this subject was read by Liverpool Diocesan Conference last year. Forwood, Chairman of the Insanitary Committee of the Liverpool Corporation, which will be for other interesting matter of a kindred nature. *SANITARY RECORD* (December 15, 1883) journal, I may note, has devoted a considerable portion of its valuable space to the ventilation of this important question for many years past.

After studying the question carefully, Mr. Forwood declares his conviction that when it is clearly established that the public health is endangered by the overcrowding and insanitary houses, private enterprise is unable or unwilling to deal with the evil, it is the duty of the authorities to take the matter boldly and provide a remedy, even at the cost of such action may entail a loss. The Corporation of Liverpool, acting on this advice, are erecting a building at Nash Grove thirteen blocks of 12 dwellings, five storeys high, at an estimate of 55,000*l*., exclusive of the cost of the ground. Erections are also projected. (*See SANITARY RECORD* for March 15, page 437.) Mr. Forwood's opinion that the block system offers the cheapest means of providing suitable dwellings for labourers, near to their work, at low rentals, it is desirable that such rents, if possible, should not exceed one shilling per week per room. It is intended to place such accommodation within reach of the very poor. The objections on which theorists against the block system of dwellings on the score of unhealthiness, have now been exploded by the practical example gained in the numerous blocks of model dwellings which have been erected in London and elsewhere.

Dublin is another city where more than 100,000 persons are housed under Sir R. Cross's Acts has been carried out. The Corporation cleared a large area at a cost of 24,000*l*., and in order to encourage the erection of dwellings for the labouring class let it to the Dublin Artisans' Dwellings Corporation at the nominal rent of 20*l*. per annum. Encouraged, the company has already built 600 dwellings specially adapted to the requirements of the class, and are about to erect 400 more on the same site. Dr. Cameron, of Dublin, is another who is also of opinion that in default of action taken by any other agency it is the duty of municipal authorities to make some provision for housing the very poor.

The authorities of Belfast have given an impetus to the erection of houses for the working class by making a material reduction in the rates of the class of property; houses under 20*l*. per annum being allowed a reduction of 50 per cent. regular assessment: a further reduction of 10 per cent. is allowed on houses under 8*l*. per annum. As the rates are paid promptly by the tenants within a month of the date of the assessment. Under such liberal treatment it is not surprising that the working class of Belfast are much better housed in the shape of house accommodation than their brethren resident in other large towns. Their self-contained cottages of two and three rooms, with the usual conveniences, are to be had at from 10*l*. to 3*l*. 6*l*. per week, and prove amply remunerative at those figures.

In Birmingham the authorities may also be said to have led the van in sanitary reform during recent years. By their energy and liberal ex-

considerable amount of money in improvement have accomplished a complete and satisfactory in the sanitary aspect of that large important borough, including the erection of labourers' dwellings. It was stated by Dr. at the recent Social Science Congress held that he did not believe that there were more than a dozen instances of families occupying but a room to each family in that town—a marked contrast to what he had seen there before, and to what is now to be found elsewhere. The excellent work accomplished by the City of Glasgow Improvement is so well known, that it is merely to mention it as showing the good authorities can do in this direction when so advised. These authorities have set an excellent example to other Corporations.

Newcastle, where so large a proportion of the population reside in tenements of but one or two rooms, no practical effort has been made, or aid from the Corporation to provide accommodation for any hundreds of the labouring poor who have been unhoused during recent years, on account of repairs and other improvements, although the means for doing so has been freely admitted, and the purpose has been prepared on several occasions. This omission has been keenly felt by the labourers, who now find it very difficult to find a home suited to their requirements within the neighbourhood of their work. These so-called improvements have also pressed very hardly on the poor of Newcastle, as by them 22,000 persons have been unhoused, whilst accommodation has only been provided for about 14,000 on or near the site of their former dwellings. The grievance has perhaps been more acutely felt in Newcastle by the Quayside, where the only chance of a temporary job ends on their presence upon the spot when a ship or other vessel arrives. It is bitter irony to see these poor people to reside a mile or more from their work, as many are now compelled to leave their former habitations in the neighbourhood being pulled down.

The principal effort that has been made in Newcastle to meet the urgent want of dwellings near the docks was undertaken by the company with which the Corporation is connected, which, along with other philanthropic works, owes its formation to the indomitable energy of Mr. James Wilson, its present chairman. In 1870 the company erected a small experimental block of forty-four dwellings, which proved a great success. It was filled with good tenants, the demand for dwellings being much greater than the supply, and the shareholders provided most of the capital, and were rewarded with the fair dividend of 5 per cent. in nine years successively after the opening of the block, showing conclusively that in Newcastle, when properly supported, such an undertaking does not prove a bad investment, independent of the good work it may accomplish. This success induced the company to make an effort to erect a larger block, but unfortunately at that time it does not appear to have been in quite so good a state as at present, and the appeal of the Corporation for the increase of capital necessary to carry out their proposed extension met with a poor response.

It was evident that the proposed extension would have to be abandoned unless the aid of a Government loan or some other means of raising additional capital was sought. After much con-

sideration the company applied to the Public Works Loan Commissioners for a loan equal to one-half the cost of the proposed extensions, which was granted. As this loan is repayable, both principal and interest, in heavy annual instalments, it formed a somewhat serious charge on the company for the first few years after it was granted, engrossing a considerable portion of the annual revenue, which would have otherwise been applicable to the payment of dividends if the whole of the capital had been provided by shareholders. A large portion of the capital sum has already been repaid, and of course the balance is reduced yearly. The shareholders will ultimately reap the reward of their pluck and patience, as their property becomes annually enhanced in value, with the advantage of undeniable security. With the aid of the increased capital thus obtained in 1879 the company extended their block by the addition of other sixty-four sets of two-room dwellings and shops—as well as a large room used for instruction and recreation. The whole of the dwellings are now fully let, with numerous applicants waiting for vacancies. This year the company paid a dividend of 3½ per cent.; their resources have been much crippled by the payment of house duty and other onerous rates and taxes, to which similar buildings elsewhere are more or less exempt. The buildings now accommodate 500 persons, chiefly of the labouring class. Of course the London companies, with a different class of tenants, and a rental at least 25 per cent. higher than can be obtained in the provinces for similar accommodation, are able to show more favourable returns, but the results will always be governed by local circumstances. For instance, whilst some of the blocks of the London Improved Industrial Dwellings Company pay as much as 8 per cent., their blocks at Wapping (which for situation and class of tenants bear the greatest affinity to the block of the Newcastle company) only paid 1½ per cent. last half-year, but from the great number of their blocks in various parts of London, which command higher rents, the company are able to equalise their dividends and pay a uniform 5 per cent. It has been suggested that the Corporation of Newcastle might well follow the example of the authorities I have quoted; for, with the abundance of land of their own in eligible situations at their disposal, and with a competent official staff, they are able to erect a large block of dwellings for the labouring class at a much less cost, and therefore, at a lower yet remunerative rental than can be expected of any public company or private individual who do not possess such advantages.

Beyond this, surely the hundreds of poor people who have been unhoused by the Corporation during recent years have some claim to their consideration. If unwilling to build themselves, the Corporation might render material assistance to those who recognise the great want of dwellings for the poor, and may feel disposed to meet it.

The principal facts that have been elicited after all that has been written and said on this subject may be thus summarised.

1st. That the poor of the labouring class, out of their limited resources, cannot afford to pay more than a rental of from one to two shillings per week for their dwellings, of whatever size and construction and wheresoever situated.

2nd. That no practical plan has yet been devised by which dwellings can be built, which, after paying a fair market price for land, labour, and material,

can be let at these low rentals and prove remunerative to the builders.

3rd. If this desirable end is to be accomplished it must depend, to some extent, on philanthropic aid, either from Government, corporate authorities, or private individuals.

4th. The most efficient aid that the Government can give is to grant loans at a low rate of interest—say 2½ per cent.—to companies who erect dwellings at a low rent for the *bona fide* poor, the repayment of such loans to extend over a longer period than is now the custom (thirty years).

5th. That it shall be incumbent on corporate authorities as the appointed guardians of the public health, where the want of proper dwellings for the poor is shown to exist, to provide sites for the erection of such dwellings; and, in order to encourage such erection, to grant a reduction of rates, or afford such other aid, as may enable the promoters to secure a satisfactory return.

6th. That the sanitary officers should take more vigorous action under the powers already conferred upon them to improve the condition of existing dwellings and the removal of nuisances, whether caused by bad tenants, or the neglect of unscrupulous landlords, care being taken to reach the real offenders.

SODA AND MINERAL WATERS.—The Commissioner of Health (Dr. Raymond), by virtue of the power conferred upon him by law, has declared the following practices dangerous and detrimental to public health, and has therefore prohibited the same in the city of Brooklyn:—(1) The storage, keeping, selling, or having for sale, of soda water or mineral water in tin-washed copper fountains or vessels. (2) The storage, keeping, selling, or having for sale, of soda water, mineral water, syrups, or flavouring extracts, in vessels composed in whole or in part of copper, lead, or other poisonous substance in which the soda water, mineral water, syrup, or flavouring extracts come in contact with the copper, lead, or other poisonous substance. (3) The selling, delivering, or draughting of soda water, mineral water, syrups, or flavouring extracts through pipes, faucets, or taps, composed in whole or part of copper, lead, or other poisonous substance, unless such pipes, faucets, or taps are so lined, coated, or protected as that the soda water, mineral water, syrup, or flavouring extracts cannot come in contact with the copper, lead, or other poisonous substance composing the same. The commissioner states that, in reference to the above declaration and order, the evidence as given in the recent hearings satisfied him that the probability of soda water and mineral water becoming contaminated with poisonous substances was very great, and that an examination just made by the chemist of the department (Dr. Bartley) confirms this opinion. In this examination Dr. Bartley visited fifty-five localities where soda and mineral water were sold. These localities were not selected, and included some of the principal thoroughfares of the city. In these fifty-five examinations copper was found in the syrup in eight and in the soda or mineral water in seventeen instances. In this tour of inspection he found but four tin-washed copper fountains in use, and in every one the soda water contained copper.

A MILKMAN DISSEMINATING FEVER.—At the Berwick Police Court, William Scott, a cow-keeper at Tweedmouth, was charged with contravention of the order of the Privy Council by allowing milk to be sold whilst there was typhoid fever in his house. It was stated that up to that time no less than twenty-three cases of fever had been traced to milk sold from Scott's house after the disease had broken out there. He was fined in the mitigated penalty of three guineas; a somewhat mysterious decision.

THE REGULATION AND REGISTRATION OF PLUMBERS.

FACTS IN SUPPORT OF THE EXTENSION OF THE EXISTING STATUTE LAW AS TO HOUSE DRAINAGE.*

By ERNEST HART,

Chairman of the National Health Society. Member of the Executive Council of the International Health Exhibition.

I.—INTRODUCTORY.

GENTLEMEN, It would ill become me, before an assemblage such as this, to arrogate any superior or special knowledge on the 'art and mystery' of proper plumbing. But it has seemed advantageous that one who, from the nature of his work and the bent of his inclinations, has gathered together some experiences of general interest on a matter that affects us all, both professionally and domestically, should offer those experiences for the consideration and discussion of an institution having functions and attributes such as yours. In what follows, I shall not attempt to indicate in detail the sanitary defects from which our houses and their inhabitants suffer. It must suffice for me to draw your attention in general terms to the undoubted evils which accompany bad plumbing and imperfect drainage, and to indicate what, in my judgment, appear to be the only effectual remedies.

It is not by any means an exaggeration to say that hardly a week passes without some mischief caused by bad drainage being brought under my notice. Epidemics caused by sewer-gas occur and recur, but their warning is not heeded. People are vaguely conscious when they get a strong whiff of sewer-gas in their houses, that there is 'something wrong with the drains,' but it does not occur to them that there is any need for action on their part until one of their household is struck down with typhoid fever or diphtheria. It is not till then that the health-officers or sanitary architect is called in, to find, it may be, that the inmates of the house have been practically living for a considerable period over a cesspool.

The effects of sewer-gas manifest themselves in many occult ways other than an explosion of actual disease. A convalescence is retarded; ordinary disorders take on more acute phases, surgical operations heal slowly and badly, the household is generally out of health, and below par. A diligent search in the basement would probably reveal the cause of all this. I shall hardly need, before an assemblage like the present, to argue that drains ought not to be improperly constructed, improperly laid, or improperly connected with the sewers. Let me endeavour to be constructive as well as destructive, and to indicate what, in my opinion, may best be done by legislation to keep from our thresholds the arch and subtle enemy of sewer-poison.

It would be foreign to my present purpose to discuss at all the various traps and other contrivances for preventing the access of sewers-gas to our houses that are so much paraded before the public. The cardinal principle is, of course, to break the connection between the air of the house-drains and the air of the sewers. Anything that interferes with this, or sets itself up in substitution for it, is a delusion and a snare. I shall presently

* Read at the Plumbers' Conference at the International Health Exhibition, Oct. 30, 1884.

explain, so far as appears necessary or the true system of house-drainage; but it is clear that, as in everything else, it is the way the system is practically carried out that is the important thing of all. Hence we are brought to the problem which I have set myself to—the best means of providing for the regular registration of plumbing in houses.

—EXISTING LAW ON THE SUBJECT.

It must be confessed that on this subject of house-drainage our existing statute law, both in the country and in the metropolis, is very insufficient and unsatisfactory.

England Generally.—Under the Public Health Act, 1875, where a house is without a drain sufficient for house-drainage, the local authority must, by notice, require the owner or occupier to provide a covered drain emptying into any sewer not more than 100 feet from the site of such house; or, if there be no such sewer, then into a covered cesspool at some other place not being under any house, as the local authority may direct. Such drain or cesspool must be of such materials and size, and at such level, and with such fall, as on the advice of their surveyor the local authority may require. If such notice is not complied with, the local authority may, after the expiration of the time specified in the notice, do the work themselves, and may recover in a summary manner the expenses incurred by them in so doing from the owner or may, by order, declare the same to be improvement expenses (sect. 23). This applies both to urban and rural sanitary districts.

It is unlawful in any urban district newly to erect a house, or to rebuild any house, which has been pulled down to or below the ground-floor, or to pull down any house so newly erected and built, unless a covered drain or drains be constructed, of such size and materials and at such level and with such fall as on the report of the surveyor may be required by the urban authority to be necessary for the proper drainage of such house. Such drains must be empty into any sewer which is more than 50 feet of the house; or if there be no sewer within that distance, into a covered cesspool (sect. 157). Contravention of this section involves a fine of 50*l.* It will be noticed that this requirement does not extend to rural districts unless the local authorities have been invested with urban powers, which are often not applied for until a number of new houses have been erected on the most insanitary principles.

The urban authority (including, of course, rural sanitary districts invested with urban powers) may make regulations with respect *inter alia* to the drainage of buildings (sect. 157). The owner and occupier of a building is entitled to cause his drains to empty into any sewer of the local authority on condition of giving due notice and of complying with the regulations of the authority in respect of the mode in which communications between such drains and sewers are to be made, and subject to the control of

any person who may be appointed by the authority to superintend the making of such communications (sect. 21). The definition of nuisance given in sect. 91 of the Act includes 'any drain so foul or in such a state as to be a nuisance or injurious to health,' for the abatement of which the proceedings specified in the subsequent clauses of the Act may be taken. Every local authority must provide that all drains, water-closets, earth-closets, ash-pits, and cesspools, within their district be constructed and kept so as not to be a nuisance or injurious to health (sect. 40). On the written application of any person to a local authority, stating that any drain, water-closet, &c., on or belonging to any premises within their district is a nuisance or injurious to health (but not otherwise), the local authority may by writing empower their surveyor or inspector of nuisances, after twenty-four hours' written notice to the occupier, or in case of emergency without notice, to enter such premises and cause the ground to be opened, and examine such drain. If the drain on examination appears to be in bad condition, or to require alteration or amendment, the local authority is forthwith to give notice in writing to the owner and occupier, requiring him forthwith or within a reasonable time to be specified to do the necessary works. Non-compliance with the notice is punishable by a penalty of ten shillings for every day of default, and the local authority may, if they think fit, execute such works, and may recover the expenses of so doing from the owner (sect. 41).

The obvious object of all these clauses is the repression of nuisance from drains where it has arisen. But for the prevention of disease by ensuring proper workmanship in the first instance there is practically no effective legislation whatever.

Powers under By-Laws.—The by-laws which individual local authorities propose for ensuring proper and adequate drainage of buildings vary of course according to local circumstances (and, it may be added, prejudices). But inasmuch as all these by-laws have to be approved by the Local Government Board, it may fairly be assumed that the model lines prepared by that Board—to which they have shown a great disposition to adhere—represent all the regulations that are likely to be put in force anywhere. These regulations require that the drains shall be of proper size, materials, fall, and position, that they shall be embedded in concrete, ventilated at each end, and that the inlets shall be trapped. The drains must be trapped from the sewer, there must be no right-angled junctions, and at least two untrapped openings as near the lower and upper extremities of the drains as practicable must be provided.

Under the Model By-laws, every person who intends to erect a new building must send in complete plans and sections of every floor of such building, together with a description of the intended mode of drainage, and a block plan showing the intended lines of drainage and the intended size, depth, and inclination of each drain, and the details of the arrangement proposed to be adopted for the ventilation of the drains. Before covering up any drain the builder must send a notice to the surveyor of the date when the drain will be covered up. If he neglects to give such notice (and in that case only) the surveyor may have the work cut into, or laid open, or pulled down if he cannot otherwise ascertain on inspection whether the by-laws have been contravened. The surveyor is to have free

is defined by sect. A of the Public Health Act to mean of and used for the drainage of one building only, or pre- n the same curtilage, and made merely for the purpose of ting therefrom with a cesspool or other like receptacle for r with a sewer into which the drainage of two or more r premises occupied by different persons is conveyed.' the same definition is given in sect. 250 of the Metropolis ct Act, 1885.

access to the work at all reasonable times for the purpose of inspection during construction, and also within a period of seven days after the completion of the building. But the surveyor cannot claim to render the occupation of a new building conditional upon his certificate as to the structural and sanitary fitness of the premises. And, generally, it must be borne in mind that these by-laws are not of universal application. The local authority have first to be convinced that by-laws are necessary, then to discuss with the Local Government Board the details of their proposals, and, finally, when at length they have the power of regulating new buildings, have to make up their minds to enforce such power. Very many sanitary districts in the country have still no building by-laws at all, and the jerry builder has therefore ample opportunity throughout the kingdom for his malevolent enterprise.

(b) *Metropolis.*—In the metropolis a little more is regulated by Act of Parliament, but there are no by-laws in force which impose the useful regulations contained in the Model By-laws of the Local Government Board. Thus sect. 73 of the Metropolis Management Act, 1855, makes obligatory the provision of proper drains to every house required by section 23 of the Public Health Act of 1875, but goes a little more into detail, and provides that it shall be lawful for the vestry or district Board of Works to 'cause the said works to be inspected while in progress, and from time to time during their execution to order such reasonable alterations therein, additions thereto, and abandonment of part or parts thereof, as may to the vestry or Board and their officers appear, on the fuller knowledge afforded by the opening of the ground, requisite to secure the complete and perfect working of such works.' Sect. 75 of the same Act prohibits the erection of a new house unless a proper drain be provided; and sect. 76, as amended by sect. 63 of the Metropolis Management Act, 1862, requires that seven days' notice to the authority must be given of the intention to lay or dig out the foundation of a new house or to make any drain under a penalty of 5*l.* and 2*l.* a day. Every such foundation must be laid at such level as will permit the drainage of such house in compliance with the Act, and every drain must be made in the 'direction, manner, form, of the materials and workmanship, and with such branches, &c., as the vestry shall order, and every such drain shall be under the survey and control of the authority.' Sect. 82 gives the authority power of inspection of drains at all reasonable times in the daytime, and power to open the ground in any place they think fit. Improperly making or altering drains is punishable by sect. 83 by a penalty of 10*l.*, and if matters are not remedied within fourteen days, the local authority may do the necessary work and charge it to the person offending. Drains found in bad order or condition, or requiring cleaning, alteration, or amendment, must by sect. 85 be put into proper condition within a specified time, failing which the vestry may execute the necessary work.

Thus it will be seen that in many respects the metropolitan law is inferior to the law for the provinces. There is no authority which can enforce the enactment and practical carrying out of adequate by-laws; the Metropolitan Board of Works, which can control the foundations and the stability of buildings, has no power over their drainage; but all

is left to be regulated by the local vestries attempt at any sort of consistency or success. Hence it is not surprising that the state of house-drainage of the metropolis should be so scandalous as it is admitted on all hands to be by one who takes a walk through any of our suburbs, and who contemplates the flimsy structures that are being run up on all sides, can feel impressed with the store of mischief that is being laid up for the next generation, if not for the present, through the absence of effectual regulations for the control of building and drainage operations.

III. UNIVERSALITY OF BAD DRAINAGE

This somewhat tedious exposition of the law has been a necessary preliminary to a discussion of the alterations and additions which are to be made in it for the complete protection of the householder. I shall not here enter at all into the respective merits and demerits of the various systems of house-drainage, nor into the merits of the multitudinous traps and other contrivances which are so much belauded by their inventors; but I shall insist upon, and endeavour to show the necessity of, stringent regulations designed with the object of insuring that no drainage work is done except by properly instructed and skilled plumbers, and further, that each stage of such work is systematically and thoroughly inspected by an official local authority, who shall test the efficiency of the drains before allowing them to be covered, and whose certificate shall be essential before a house can be occupied.

Sanitary Condition of Private Dwellings in Rogers Field, than whom no greater authority exists, recently summed up the principles governing house drainage as follows:

1. All refuse matter must be completely and rapidly removed from the house.
2. There must never be any passage of air from the drains or waste-pipes into the house.
3. There must be a direct connection between the drains and the water-supply. These, although so simple, are so frequently neglected. The first goes absolutely to the root of sanitation, for were it strictly complied with there would be no leaky drains, no polluted drains, and no production of foul gases in the drains from decomposing organic matter. The number of houses fulfilling the conditions described in Rogers Field is surprisingly small. Mr. Field himself said at a recent discussion that 'from my experience of eight or ten years in these houses he found that the majority of houses were defective, and out of about a thousand examined he had only found three that were perfect.' The resident engineer of the London Sanitary Association, stated last January that of the houses inspected by his Association, total disconnection or stoppage of the drains had been detected in 6 per cent., leaky soil-pipes in 31 per cent., disconnection of the sinks, baths, or fixed basins, in 18 per cent., drain or soil-pipe in 68 per cent., and direct communication between the drinking-water cistern and the drain or soil-pipes in 37 per cent. From 100 country houses inspected by the Edinburgh Sanitary Inspection Association, 90 per cent. had their drains in direct communication with the exterior; 80 per cent. had faulty water storages

* SANITARY RECORD, Vol. xiv., p. 209.

† *Ibid.*, Vol. xiv., p. 313.

‡ *Ibid.*, p. 313.

its; and no less than 15 per cent. had the main trunks in direct connection with cesspools. And a every-day experience it is impossible to doubt: the number of houses that can be regarded as: from the irruption of sewer-air is very small indeed. Our public buildings, where economy not be pleaded as an excuse, do not set us the example they ought. The imperfect sanitary condition of the War Office, of Somerset House, and Local Government Board and of other Government offices, has at various times monopolised a large share of public attention, and we hear too much of public buildings, hospitals, asylums, and the like, being rendered unbearably offensive and even dangerous to life through the imperfect state of their drainage arrangements.

—NATURE AND EXTENT OF MISCHIEF CAUSED BY BAD DRAINAGE.

Although no sanitary evil has been more abundantly demonstrated than defective drainage, it is unfortunately possible to adduce any statistical evidence of the mischief which it causes. For when individual members of particular households are sickened down by illness arising from this cause, it is done that the mischief is known outside the family circle, unless he or she chance to be a person of importance. The Prince of Wales's illness in the winter of 1870, the Duchess of Connaught's recent experience at Bagshot House, have their counterparts by hundreds; but the public does not know of them except by accident. It is only when fever-poison gets distributed wholesale through sewers, and obtains access to the interior of houses through imperfect house-drains that the evil is seen in its true light. The number of deaths which drain-air is an existing or a contributory cause is not ascertainable from the Registrar-General's returns; but if we bear in mind that sewer emanations and polluted waters are the two chief agents in the production of typhoid fever we may, without fear of contradiction, assess the annual number of victims to drain-air almost by thousands. The evil with which we have to cope is, therefore, one of very general and pressing importance.

V.—RECOMMENDATIONS FOR STRENGTHENING THE LAW.

Imperfect Recognition of Danger of Communication of House-Drains and Sewers.—Amongst those who are immediately concerned in the erection of buildings there seems to be a very imperfect recognition of the danger involved by the direct communication of the sewers with water-closets, sinks, lavatories, baths, and the like in the interior of the houses. And, in regard of construction, almost unlimited trust has been placed in artisans, who not only can hardly be expected to understand certain of the first conditions (as to atmospheric pressure) which they have to meet, but who also in not a few instances have evidently failed to apprehend that even their mechanical work requires conscientious execution. Under influence of the latter deficiency there have been left in innumerable cases all sorts of escape holes for sewer effluvia into houses, and leaky drains effusing their filth into basements; while under the other deficiency, house-drainage, though done with good workmanlike intention, has often, for want of skilled guidance, been left entirely without exterior ventilation, and sometimes has in

addition had the overflow-pipes of baths or cisterns acting as sewer-ventilators into the house; and all this not unfrequently in places where the sewer itself, from which so much air has been wasted, has been an ill-conditioned and unventilated sort of cesspool.*

Thus, the two great evils to be guarded against are (1) *improper systems* and (2) *imperfect workmanship*. The first can only be guarded against by the definite prohibition by Act of Parliament of all such improper appliances as D-traps, containers of the like, and by insisting upon the disconnection of the air of the sewers from that of the drains. The second can only be prevented by the systematic instruction of plumbers in their craft, by imposing the necessity of a licence on all plumbers, and by adequate independent inspection of all drainage work before it is covered up and lost to the view. It is unnecessary for me, before such an audience as this, to go minutely into the quality, material, or other details of the system of drainage to be adopted. It will suffice to state certain broad general principles, the reasonableness and necessity of which will, I think, be readily admitted.

Systematic Instruction of Plumbers.—The systematic instruction of plumbers in their craft is no doubt a matter outside the Legislature. But much may be done by the delivery of lectures, such as the admirable series recently given by Mr. Stevens Hellyer, under the auspices of the National Health Society, and now published in a separate and attractive form.† The interest, and even enthusiasm, with which these lectures were attended by working plumbers is, I hope, a fair augury of better things in the future. The City Guild of Plumbers, which has recently shown signs of awakening life, might, moreover, do much to encourage good and discourage bad work by instituting a School of Plumbing, with the needful accessories and workrooms, as well as by the exercise of its influence upon the trade.

And if I may venture a suggestion to architects as a body, I would advise that in their specifications they should be more definite as to the nature of the appliances ordered, and should exercise supervision over these being properly situated and connected. I trust I shall not be unduly touching upon the ethics of the profession when I remark upon the immense advantage which accrues from the architect insisting upon personally testing and examining the pipes and drains of any house which he has designed before they are covered up and lost to view. If every architect did this as part of his professional concern for the house, we should hear much less often of death and disease caused by drain-air.

Turning now to the question of the strengthening of our statute law as to drainage and plumbing, I think that in any new Act the following points should be provided for:—

First as regards *drainage itself*:—

1. Rural authorities should have the same powers as are now possessed by urban authorities. In the suburbs of towns, just outside the municipal boundaries, thousands of houses are springing up without any sanitary supervision whatever. The rural authority is, perhaps, unaware of the evil, or is, at any rate, careless about it, until the houses are erected; and their opportunity of making by-laws which can control such houses is then lost.

* Simon, 'Report on Filth Diseases,' p. 25.

† 'Lectures on the Science and Art of Sanitary Plumbing,' by S. Stevens Hellyer. S. T. Batsford.

2. It would be well that the requirements of the Model By-Laws as to New Buildings issued by the Local Government Board should be incorporated in a Building Act, which should be forthwith passed, and be of general application throughout the country.

3. The plumbing and drainage of all buildings, public and private, should be executed in accordance with plans and specifications previously approved in writing by the local authority.

4. No drainage-work should be allowed to be covered or concealed in any way until it had been examined and passed by the surveyor.

4A. The efficiency of all drains should be tested by the peppermint or some other test before they are passed; and it should be a rule that, wherever possible, drain-pipes should be kept from view only by boarding which can be readily removed.

5. No new house should be allowed to be inhabited until it had been passed and certified by the surveyor, and a plan of the system of drainage should be appended in every case to the lease or other document for the letting of the house.

As regards the *plumbers*, I suggest that—

6. The names and addresses of all plumbers should be registered by the local authority, and no plumber should be able to carry on his trade until he had been so registered, and had received a licence from the local authority.

7. Before the licence is granted to him the plumber should attend personally at the office of the local authority, for examination as to his qualification as a plumber.

8. Such licences should be renewed from year to year, and their continuance should depend upon the good behaviour of, and the return of the work done by, the licensee.

9. The names of all licensed plumbers should be publicly advertised once a year by the local authority.

VI.—STATE OF THE QUESTION IN AMERICA.

If it be contended that the enforcement of such regulations as these would harass a particular calling, and be an unwarrantable interference with trade, my answer is a reference to the enormous evils which arise from imperfect drainage, and an appeal to what is now taking place on the other side of the Atlantic. In the United States—the 'land of the free'—the plumber is being sternly circumscribed in his powers of mischief. All the more important towns are taking powers for the registration of plumbers and the regulation of plumbers' work, and I cannot do better than cite in conclusion what has been done in this regard.

The State of Illinois claims to have been the first to have passed a law for the regulation of plumbers, though it would appear that the subject had for some time before the Illinois Act was passed been under consideration at New York.* The effect of the Illinois law, which was passed on May 30, 1881, was to make compulsory the sending in to the Health Commissioner and approval by him of the plans of all new buildings, and to prohibit any plumbing work being covered up until approved by the Commissioner under a penalty of 100 dollars. It will be observed, however, that no provision is made here for the registration or licensing of

plumbers. Chicago promptly took advantage of the law with the best results.

New York has passed a law in the spring (and which is applicable to New York and Brooklyn), making the registration of plumbers compulsory, and providing for the supervision of plumbing and drainage generally. Every master and man plumber must register his name and address with the Health Department of the city, and no man may carry on the trade of plumbing unless he is registered. A list of the registered plumbers must be published once a year. No building erected the plan of which has not previously been approved by the Board of Health; and drawings must also be submitted and deposited with the Health Department, and everything which relates to the plumbing and drainage of the house. Before the drains are covered up notice must be sent to the Health Department by the owner or plumber, and the inspector may examine the work, and the Health Department will not approve or permit a drain to be covered up until it has been examined by one of its inspectors and found to be properly constructed.

The Boston regulations, passed on January 1, 1882, are very full and complete. They are given *in extenso* in the SANITARY RECORD for last (p. 305), but I subjoin the regulations as to the steps to be taken by the Board of Health before a person may carry on the business of plumber. Every person who has not first registered his name and address with the office of the Inspector of Buildings. Every person is required, before constructing new work or repairing old work (except repairing leaks), to file at the office of the Inspector of Buildings a notice of the work to be performed, and if the approval of the Inspector cannot be obtained, the plumber is deterred from doing the work. Every house or building separately and independently connected with the public sewer. No pipes or other fixtures covered or concealed in any way. The work to be covered until examination by the inspector has taken place. The peppermint test is required if the work does not stand the test, all water turned off from the building, and not let until the plumbing has been pronounced satisfactory by the inspector. Violations of the Ordinance are visited with penalties ranging from 20 dollars.

At San Francisco there is a Board of Examiners who examine all applicants for registration as master or journeyman-plumbers, and on passing issue commendation certificates of registration. Candidates for master-plumbers undergo a theoretical examination as to the principles of plumbing, and candidates for journeyman-plumbers an examination as to the practical part of the trade.† At Washington no person may do any plumbing work of any house—which is subject to strict regulations as regards materials—covered or in any manner hidden from view until after inspection and approval by the inspector of plumbing. The pipes are to be tested with water. The police are instructed to arrest any one found making an excavation in the street or making any sewer connection without permission.

Other large towns are waking up to their responsibility in this matter. Baltimore

* See SANITARY RECORD, March 13, 1881, p. 345; and May 15, 1881, p. 438.

† SANITARY RECORD, vol. xii., p. 55; and vol. iv., p. 1.

just (October 1883) passed an ordinance providing for the appointment of an inspector of plumbing, and forbidding any plumbing work without a permit under penalty of 5 dols. Washington has also appointed an inspector of plumbing, after a four years' struggle by the medical officer of health. A very elaborate code has been drawn up for Philadelphia, but is not yet in force. They are much of the same character as those in force for New York, and need not therefore be further described.

I think these facts are a sufficient answer to possible objectors as to the character of my proposed regulations; and in any case I feel confident of your support in my contention that our building laws need thorough amendment and reconstruction.

VENTILATION OF THE OFFICES OF THE 'DAILY TELEGRAPH.'—In the compositors' room of this establishment 170 men work throughout the night, and 70 argand burners light the desks. The complaints of the men and their sufferings were very great. The proprietors, desirous of remedying this state of things, under the advice and direction of Messrs. Arding, Bond, and Buzard, have put a new and lofty roof, which is covered by a lantern along its whole length, the windows on both sides of the lantern opening in two divisions by lever bars at each end of the room; this provides an ample outlet for the vitiated air in summer time or in calm, moderate weather, when open windows are unobjectionable. Fresh, purified air, either cold or warm, is driven in by a 16-inch *Eolus* waterspray ventilator fixed in the basement. In warm weather this cool, fresh air is used to keep down the temperature to an agreeable point, while in winter the fresh air can be raised in a few minutes to a temperature of 100° by simply lighting the gas burners around the tubes through which the fresh air passes. Thus a continual supply of fresh air, equal to five times the cubical contents of the room, is afforded every hour, and of a temperature adapted to the sensitiveness of men engaged in sedentary occupation. Returning to the subject of extraction, when the weather is such as to render open windows undesirable, and in this climate of ours such an objection certainly obtains during eight months out of the twelve, the vitiated air is drawn off by two 16-inch *Eolus* waterspray ventilators, which have their communication with the composing room through two panels, occupying the position of two of the side lights of the lantern. These are continued by 16-inch galvanised shafts outside the roof, entering the composing room through the roof by the plate, and descending through all the floors into the basement. In each of the last 6-foot lengths of these shafts a waterspray is fixed; by simply turning a tap a powerful exhaust is immediately set up, dragging down the vitiated air from the composing room into the base. Thus a continual change of atmosphere is ensured for the composing room, although the doors and windows be tightly closed. Another peculiarity in this application of the waterspray as an exhaust is the fact of the upper part of the shafts falling down the slope of the roof being exposed to the action of the cold atmosphere outside; this instantly condenses the carbonic acid held in suspension in the heated air, which by its own gravity assists the downward current. Thus condensation, a feature which in automatic exhaust ventilation is always found to be an obstacle and a drawback, is here impressed into the service of the cause. A large portion of the vitiated air drawn off by the *Eolus* from the composing room is condensed and absorbed by the sprays and passed off with the waste water. The residuum, which is almost wholly pure air, passes through the shaft room into the engine room, which is again emptied by another exhaust *Eolus*, discharging into the courtyard.

The Worshipful Company of Founders have granted a donation of five guineas to the National Health Society, 44 Berners Street, W., for the Diffusion of Sanitary Knowledge.

FIGURES, FACTS, AND FALLACIES.

By EDWARD F. WILLOUGHBY,

M.B. Lond., S.Sc.C.Camb., Cert. Pub. Health, Lond. Univ.

VITAL statistics form so large and so valuable a part of the literature of public health that it is of the utmost importance that the principles and practice of the science should be well understood. It has been said that figures may be made to prove anything, and so they may if ignorantly or dishonestly handled; but since the effects of social or material agencies acting slowly on large masses of people can only be appreciated by their results as shown by vital statistics, a knowledge of the fallacies incident to such conclusions is absolutely necessary for the avoidance of erroneous inferences.

This may seem a truism, but partly from the absence of any text-book on the subject and the scanty treatment it has hitherto received in works of a general character, and partly from the idea that figures speak for themselves, some of the fallacies we are about to expose are constantly met with, not only in society and general literature, but, where we should least expect them, in the reports of medical officers of health, and thus either mistaken notions are perpetuated, or the true indications are lost sight of, and the science itself is discredited.

Of course the great storehouse of facts and figures is the office of the Registrar-General, whence are issued the reports of the census, which is taken once in every ten years (too long an interval), and weekly reports of births, deaths, and marriages, as well as quarterly and yearly summaries and a valuable decennial retrospect, in which the lessons and results of the preceding period are discussed.

Birth, death, and marriage rates are calculated on the population per 1,000, or for some purposes per 10,000. The actual population is known only by the census, but for the intervening years what are called corrected estimates are made use of. These are obtained in one of two ways, or by a combination of the two. One is that of assuming that the population continues to increase at the same rate as it did in the preceding decennium; the other is to ascertain by the last census the average number of persons 'in each house' and to assume that the same density is maintained in the following years, the number of inhabited houses being always known from the books of the rate collectors. Both methods are obviously open to error, for a population may increase rapidly through the rise of a new industry or watering-place, and then remain stationary or even decline, and the new houses may be of a better or lower class than the older ones, and therefore have a different number of occupants.

Fallacies of Estimated Population.—In 1871 it was found that the population of Gosport had been over-estimated by 33 per cent., and that of Cambridge under-estimated by 16 per cent., consequently the former had appeared healthier and the latter unhealthy than it really was, the death-rates differing not by 12 per cent., as had been imagined, but by 0.2 per cent. only.

If the assumed population differ from the true one by no more than 10 per cent., an assumed death-rate of 24 per 1,000 will represent one of 21.6 or of 26.4, as the case may be.

Fallacies of Registration.—All deaths (except those of infants under a week old, who are often reported incorrectly as stillborn, and therefore in

this country are not registered) are registered, but a large number of births escape registration either from negligence, shame of illegitimacy, or for the purpose of avoiding vaccination.

Fallacies as to Causes of Death.—In many parts of the country a large proportion, in the mining districts of Wales and Durham as high as 10 to 14 per cent. of the causes of death are entered by the registrar on the evidence of the friends, or are suggested by himself in the absence of any medical certificate. Thus the apparent prevalence of 'consumption' in Wales is partly due to all lingering diseases being so-called by the ignorant people. Even medical certificates are very often inaccurate, either from faulty diagnosis or from the patients having been attended by unqualified assistants, or, as is not unfrequently the case in rural districts, seen by the medical man only once before death.

Definition of terms employed.

Mean age at death	}	Sum of ages at death
		Number of deaths.
Mean age of living	}	Sum of ages at census
		Number of persons living.
Mean duration of life	}	Number of population
.....		Number of deaths in a year.

Probable duration of life, or expectation at birth = age at which a number, say a million born, is reduced to one-half.

This is not the same as the mean age at death, for in two communities 1 in 40 may die annually, *i.e.* 25 per 1,000, but in one the deaths may be mostly those of infants, the adults reaching a good old age, in the other few may attain a great age but the infant mortality may be low.

Natural increase = excess of births over deaths.

Fallacy of Duration of Life.—The rule given for finding the mean duration of life holds good only of the rare case of a stationary population, *i.e.* one in which the births just balance the deaths. Thus, with our present mean birth-rate of 35 per 1,000, Dr. Richardson's Utopian death-rate of 4 or 5 per 1,000 in Hygieopolis would imply a mean duration of life of 65 years and not as would at first sight appear of 200 or 250 years.

The probable duration of life or expectation is obtained from life-tables which profess to show how many of a million born die every year, until all are extinct. They should be made by watching a generation throughout its existence, but they would then be out of date, since the conditions under which these persons passed their later years might be more or less favourable than those of their youth. Actually and probably they are made more correctly by observing for a period of ten or twenty years the ages of all persons at death, and assuming the results to be applicable to the whole lifetime of each. Some, of course, were born, and passed many years under better or worse conditions, and the same will be the case with the rising generation; but the error is greatly reduced, and life-tables frequently checked and corrected are the best guides to the health of a community.

For life assurance an error in the tables giving a duration under the truth is an advantage, but the aim of the sanitarian is to falsify all tables.

Dr. Rumsey proposed as a test of healthiness what he called lines of vitality and of mortality, or the mean ages of the living and the dying. In healthy communities the line of mortality is the

higher; in unhealthy, that of vitality. Thus he found in Herefordshire the vitality = 28½ years, mortality = 38½, but in Liverpool vitality = 25, and mortality 17½—*i.e.* in the former people lived longer, in the latter they died early. But immigration disturbs such calculations; even in the rural parts of Surrey 24 per cent. of the population were immigrants.

Birth-rates and Death-rates.—The health of a people lowers the death-rate; prosperity raises the birth-rate, unless voluntary and artificial checks are imposed; but a high birth-rate, may also be due to early and improvident marriages.

Increased length of life implies a decrease of the death-rate, but not necessarily an increase of the population, which depends on the excess of births over the deaths. With a decreased death-rate there will be a larger proportion of adults if the decreased death-rate be mainly among children, or of the aged if among adults.

The death-rate is dependent on the sanitary condition of a community, and is thus under legislative control.

The birth-rate depends greatly on voluntary marriage and the fertility of females—*i.e.* on the action of individuals rather than on that of the State. It is strikingly connected with the demand for labour, with emigration, and with any need for men to fill the vacancies caused by death. Thus, after wars and pestilences a population increases rapidly, young men filling the places of the deceased and marrying thereon. Rising industries, in like manner, lead to numerous marriages and propagation. The birth-rate depends on the constitution of the population, chiefly as affected by employments; the death-rate on its constitution as regards ages and sanitary conditions.

A large proportion of aged persons by no means implies longevity, but depends on the proportion of children to adults—*i.e.* on the size of families. Thus there is a larger percentage of persons over sixty years in France than in England, not because life is longer there, but because fewer children follow each marriage; and the natural increase of the population is consequently less. The teeming populations of Liverpool and Manchester, amid insanitary surroundings and unfavourable social conditions, have the highest birth-rate; but also the highest death-rate, and are only maintained or increased by immigration.

The death-rate varies almost directly as the density of the population—not, that is to say, in consequence of mere aggregation, but from the social and moral conditions causing and caused by overcrowding, poverty, and vice. A high degree of aggregation is in itself quite compatible with a low death-rate, as in the improved industrial dwellings where one thousand persons or more are comfortably housed on an acre.

Fallacies concerning the Relations of the Birth-rate and Death-rate.—It is often said that a high birth-rate involves a high death-rate, the latter constituting a sort of natural check on the former. Of course infancy is more tender than manhood, and where there is a large infant population there will necessarily be more deaths than where children are few. But if the high birth-rate be the natural and direct result of prosperity and of high wages, as in flourishing colonies, the birth-rate will greatly exceed the death-rate, the sanitary conditions being good.

on the other hand, the high birth-rate be-
lt of general illegitimacy, of improvident
s, &c., the consequences will be a propor-
high death-rate and a teeming but short-
ulation.

tion of Infant and Child Mortality.—It is

uestion of infant mortality is closely con-
ith that of infant feeding, and these ex-
ry differences are mainly if not wholly
e in this way. In the Faroe Islands and
in infants are invariably breast-fed, while
in and among the working-classes in Bavaria
as constantly brought up on sopped bread
aceous foods. It is a fact full of instruc-
when during the sufferings and starvation
y the siege of Paris the general mortality
lation was doubled, that of the infants was
by 40 per cent. simply from the mothers
mpelled to suckle their babies, and the

same increase of the adult and diminution of the
infant mortality was observed during the Lancashire
cotton famine when the mothers were no longer at
work in the mills.

When improper feeding is the chief factor, a large
proportion of the deaths are due to diarrhoea and
other diseases of the digestive organs, convulsions,
&c., and relatively fewer to other causes of a less
preventable kind.

Fallacious Inferences from Neglect of the Factor of Age.—Since of the 20 deaths per 1,000 living in
this country 8 on an average are those of children
under 5 years, 8 of persons between 5 and 65 years,
and 4 of still older persons, or 40, 40, and 20 per
cent. respectively of the deaths are contributed by
these age classes; and since infancy and childhood
are more susceptible to insanitary influences, it is
obvious that the general mortality will be greatly
affected by the relative proportion of children and
adults. Indeed, Dr. Rumsey showed that the dif-
ference of 10.5 per 1,000 in the death-rates of Dr.
Farre's 60 healthiest and 30 unhealthiest districts
was thus explained to the extent of 8 per 1,000,
depending on the number of children and the greater
or less mortality among them.

We may here refer to a notion which has
fascinated some minds fond of paradox, and which
we may call the *fallacy of the substitution of
diseases*. It has been said that the reduction of
one cause of death leads to an increase of others.
In one sense this is true, since everyone must die
at some time from some cause or other; but the
success of sanitary measures is seen in the re-
duction of deaths from preventable causes. But
the fallacy referred to consists in ignoring the in-
fluence of mean age on the prevalent diseases. Thus
of 1,000 persons dying from all causes in 1861 to
1871, there died of:

	Scarlatina.	Consumption.	Cancer.
In the healthy districts....	2.4	108.5	27.5
In Liverpool.....	38.3	96.6	9.9

These are diseases respectively of early, middle, and
advanced life. It is not that there was less phthisis
or cancer in Liverpool, but so many persons died in
youth that fewer attained the age at which they
became liable to those diseases. Thus, an increase
in the deaths from diseases incident to advanced life
may really indicate a general prolongation of life
from improvement in the public health.

THE ATKINS FILTER AND ENGINEERING COMPANY,
LIMITED, have received an order from Her Majesty's
War Office for 40,032 lbs. of their specially prepared
Granulated Charcoal, to be used in the 'Atkins' Filters
recently supplied by them for use in the Military Barracks
and Hospitals, &c.

WE are glad to note that the City Engineer of Liverpool,
Clement Dunscombe, Esq., M.A., M.Inst.C.E., has been
awarded by the Jury Commission at the International
Health Exhibition a Gold Medal for his designs for
Artisans' and Labourers' Dwellings, and the Corporation
of Liverpool have been awarded a Diploma of Honour
for the exhibit. These designs embrace the Nash Grove
Dwellings now being erected by the Corporation under
Mr. Dunscombe's supervision, at a cost of £53,000,
exclusive of the value of the site. Descriptions of these
dwellings will be found in the SANITARY RECORD for
Dec. 15, 1883, p. 291, and March 15, 1884, p. 437.

SANITARY PROGRESS AND APPRECIATION.

By HENRY M. MAVOR.

It may be safely affirmed that in regard to general sanitation we are wise in our generation, but it must also be admitted that the present generation in the earlier years approached the subject somewhat tardily; and, furthermore, while recognising the many evils to be combated, the general public treated the danger somewhat disrespectfully, and took but few steps to ascertain causes when effects were only too palpable and fatal. In many cases of indisposition and sore throat or other pertinent ailments, 'change of air' was and is rightly insisted on, but frequently in ignorance that the 'air' which naturally was not 'suitable' contained a considerable quantity of sewer gas. It was only in the event of severe illness or fatal results that the question of drainage was taken into consideration, and this is not to be greatly wondered at, as no general attention had been called to the subject, and, owing to this want of knowledge, it was a first experience from a householder's point of view, and as such was, as a rule, dearly purchased. The sanitary surveyor, or engineer, as we understand him now, was not in existence, and the warning voice was raised by the doctor. The cause being thus discovered, the inefficient services of the plumber or builder were called into requisition, and a general patching up of drains, with the addition of a trap here and there, mended matters more or less for a time, until the still present defects that were manifest were made manifest to the occupier. In a commercial age this want of knowledge of construction soon found the correlative supply, and being a fresh field for energy and ingenuity, there was no lack of competitors to undertake the work and meet the requirements in a practical and scientific manner. Still, the public attention or appreciation somewhat flagged, except under exceptional circumstances, and it is but comparatively recently that a sense of the great importance of the question seized upon the minds of the multitude, and for the past few years a growing disposition has been evinced to at any rate take an interest in and understand the rudiments of sanitation, so far as it pertains to the immediate surroundings of the people. This advancing interest led up to and has been greatly fostered by the well considered Exhibition at South Kensington, and the lessons to be there acquired have penetrated far and wide. Many of the mysteries which were supposed to surround this study have become gradually dispelled, and it is seen that common-sense principles are brought to bear upon ordinary physical facts, and the laws of nature are enlisted in the service and not set at defiance, as was formerly the case.

But if, on the other hand, we turn to see what our neighbours are doing we find a state of things which is pre-eminently unsatisfactory. The prevalence of cholera on the continent, with such terrible results, is a strong commentary upon the gross state of ignorance, and, one might also say, wilful negligence, of the commonest forms of precaution or cleanliness. Those who have had experience in foreign hotels or houses can bear out this statement, and the indifference with which such affairs in normal times are treated is a matter of surprise and horror, not unmingled with disgust,

but which in our security we can but treat with sympathy. To 'see Naples and die' has now a terribly literal meaning. The following extract from a letter quoted in the *Times* emphasises the many sad reports: 'It may easily be imagined that a vast amount of filth has been accumulated century after century by an ever-increasing population. It is only necessary to cut brief trenches in old Naples to find a subsoil black and mephitic, because composed of organic *débris* in slow or active putrefaction. To this be added a most imperfect sewerage system, the walls of which are unprotected, without any fall, without a course of water, often placed under the level of the sea, and one can readily imagine again the putrid exhalations which arise, and which, filtering into the cisterns, poison the drinking water of the city. At present Naples is a disgrace to civilisation and humanity, and, what will come nearer to the feelings of Italians, it is a national danger.' When the disease has run its course, and the danger is past, will they, *can* they set their houses in order, and give reasonable sanitation to their city? It is of extreme doubt, if we judge by what has been done before.

In Paris the present condition is almost as serious; and the predisposing causes of infection are many. Typhoid fever is very rife, and the Seine is a distributing agent of disease, and to the defects of the city drainage may be added a supply of inferior water. We see, however, that it is proposed to institute a municipal sanitary service in Paris, which will take upon itself all the functions usually performed in England by vestries, district boards, commissioners of sewers, the Metropolitan Board of Works, and water-companies, as the management of the water-supply is to be included.

The Spaniards have barely sufficient water for drinking, therefore there is little for washing or drainage purposes. Not that they possess any appreciable system of drainage; but this perhaps is well for them, for the hot dry air sufficiently deodorises and oxidises the products of sewage, and they escape some of the risks of contamination by water.

In Germany but little encouragement comparatively is given to sanitation, although official sanction is given in high quarters to departmental efficiency. To see ourselves as others see us is always more or less amusing, if not instructive; and it will be amusing to many to hear a German professor's view of the International Health Exhibition. He reports to his 'Society' that, from a scientific point of view, it is pitiful, 'it being anything rather than its name implies.' The statement shows anything but a healthy exhibition of judgment, and its very absurdity carries its own refutation. We look in vain through all the foreign sections of the Exhibition for any real improvements in sanitary appliances or methods, and, beyond a few drawings in the French and Belgian Courts, we see no attempt to approach the subject in such a way as to require any serious attention. Perhaps this was all our German friend could find, and this might give rise to his remarkable want of perception. The literal meaning of 'approaching a subject without prejudice' is 'knowing nothing about it:' could the professor have been prejudiced or otherwise?

In America, where they have less to unlearn, they are keeping step with us, for, although 'we speak their language so badly,' they are not above exchanging views, nor are we above borrowing from

mutual advantage. The business-like and the way in which they treat the subject, both in practice and theory, is characteristic, and their agencies and other institutions for spreading practical knowledge are well considered.

Coming to the appreciation of the question at hand, we find necessary attention called from time to time in the columns of the daily papers, and it appears from all sorts and conditions of men, whether with or without a knowledge of what is writing about; but, such as they are, they tend to awaken, or, we might almost now say, to interest in work which has hitherto been, at best, a dead letter with so many.

Well-known London architect, continuing the thread in the *Times*, points out that there is interest, especially in London, absolutely no one interested it is to see that the buildings are in perfect stronger or better than the *minimum* acts of Parliament require, and there is no force dealing with the drains and sanitary within the house; though elsewhere many are acting as urban authorities under Mr. Cross's new laws issued by-laws relating to these, and will if only their inspectors are competent and to prevent a great many defects which in we suffer from. This last sentence means a deal, and Dr. Alfred Carpenter, the chairman of the Council of the Sanitary Institute, replies and says that it is not every local authority which is perfect in its reports, because inspectors themselves are sometimes quite ignorant of true principles of sanitary science. That one officer recommends, another, without condemnation as utterly inadequate, useless, or even useless. If local authorities would employ their local surveyors and inspectors of houses having the diploma of the Sanitary Institute of Great Britain, they will be certain of employing officers fully competent to make the reports which are so necessary for the promotion of the health of the inmates of all.

The law requires that local authorities should do these matters, but it does not compel them to appoint competent officers. This result may be brought about by public opinion, or may be evoked by the judicious action of the press. Another point referred to is the difficulty private persons have in deciding which are the best forms of sanitary apparatus and appliances to use, and we are afraid that the ordinary tradesman, unless he receives a competent opinion, is more puzzled than ever when the various proposals are placed before him. The conclusion of Dr. Carpenter's letter points a moral, and suggests a

'If persons in this difficulty will visit 74A, St. Street, which is the home of the Sanitary Institute, as well as the "Parkes Museum," they will see for themselves the different kinds of apparatus and appliances. They will see the forms which have won prizes and medals at different sanitary exhibitions, and which are sanitariously correct. The door is open to the public free of charge. It is a comment upon the difficulties of sanitary science when we see two bodies like the Parkes Museum (which has been organised for the purpose of

instructing the people as to what are the best forms of sanitary apparatus) and the Sanitary Institute of Great Britain, whose *raison d'être* is the education of the lower grade of sanitary officials, languishing

for want of funds and popular support, while your columns teem with compliments which could not arise if the public knew the advantages which would accrue to them from a further development of the two above-named institutions.'

Other letters contain complaints, and give examples of defective principles and construction, which are well known in professional circles, but probably have a touch of novelty to the writers and to the majority of the readers. Great stress is laid upon the fact of so many of these defects occurring in West-End houses; but as the whole system of house drainage is wrong, it is but natural that the wealthier portion of the community should take the first steps: hence the individual cases of alteration which are becoming so numerous are merely indications of the march of progress.

The obvious, but none the less useful, remedy is advocated—that intending leaseholders or purchasers should, before transacting business, insist upon receiving a certificate or report from a qualified surveyor; and if it were done it would go far towards a satisfactory solution of the subject. The testing of drains is also adverted to, and an architect writes:—'For some years hardly a week has passed in which I have not had to test drains by having them filled with water; and I only recollect one case of drains standing that test, unless where they had been very recently laid under the superintendence of a good sanitary surveyor, or by builders who had been recently trained in the system now used by our most able men. No drains should be accepted as perfect until they will stand this test, and I have generally found good builders glad to have the test applied so that their work could be guaranteed.'

Appreciation of true principles is shown by the allusion to the excellent sanitary arrangements of the latest phase of London house-building—viz., Flats, which, being carried out under the supervision of skilled architects, as a rule leave nothing to be desired. A leading example of this class of work at Brighton was lately noticed (*see* SANITARY RECORD for September 15, page 102), where the building-owner obtained considerable professional attention by the thorough manner in which the scheme was carried out. Evidences of this kind are not wanting to prove that correct views are making headway rapidly, and the majority of publications recently issued show that the science may safely be left in the hands of its present exponents. Further signs of progress are evinced by the measures being taken to counteract the pollution of rivers, the abatement of smoke, the agitation as to the disused burial grounds, the destruction and disposal of refuse, the Adulteration Acts, the proved fallacy of quarantine, and kindred subjects—a long and formidable list. We may flatter ourselves that we are in advance of other nations in these respects, but our requirements are much greater; and although the evils have been recognised for a long time past, it has necessarily taken a long time to clear the way to institute methods of procedure to counteract the influences of a long period of neglect. It is not to be supposed that a short lifetime can atone for the deficiencies of centuries.

A contrast to this perhaps congratulatory picture may be found in the doleful utterances of Dr. Norman Chevers, the President of the Health Section of the Social Science Congress. This gentleman's experience is very great, and it is therefore

discouraging to hear his views, although the disheartening effects are considerably lessened when it is found that his propositions for reform are of such a comprehensive nature as to practically deny the admission of the word 'progress.' Nothing short of absolute perfection in a comparatively short time is admitted; and here again we are met by the difficulty of defining a limit to the period in which such a desirable state is to be brought about. 'No power of concentrating language would enable us to detail, within a space of twenty minutes, even a bare list of grave sanitary shortcomings which every stranger must perceive within a week after he sets foot on British chalk.' Referring to the fallacy of placing dependence on death-rates, which, of course, depend greatly upon local circumstances, another grievous factor in the calculation is mentioned—viz., drink; and in this respect we fear the English nation cannot show a clean bill, or compare favourably with southern countries, although, with regard to those races of equal latitude with our own, it is doubtful if we differ much at *pro rata* with extent of population and the temptations and facilities thereby offered. The 'latrine on the lobby' is condemned, and the 'diphtheria-traps and plumbers' hunting-grounds' certainly do not compare favourably with the medieval 'latrines,' the artistic construction of which received no scientific aid. But 'circumstances alter cases,' especially 'reduced circumstances,' as the cynic has stated; and the requirements of the inhabitants of a fortified castle are not those of the dwellers in cities and towns in which the insanitary evils are not only aggravated but induced by the reduced circumstances, or, in other words, the want of means for prevention or remediation. To place these necessary latrines in detached towers may be desirable, but the existing conditions will not allow of it; and to do so in all future works brings us again face to face with the item of expenditure, and to devote money and space to a portion of the building which is usually relegated to out-of-the-way corners is too sweeping a measure for general adoption. True it may be that forty years ago many of the great sanitary questions were nearly as advanced in men's minds as they are at this moment; but were they as advanced in material fact? Dr. Norman Chevers advocates the appointment of a Minister of Public Health, invested with great powers, against which all narrow self-interested opposition will be futile, and commanding large means (money again!). Then, and then only, will it be found that these great questions are to arrive at a practical solution; 'not as you are working now—struggling decade after decade for certain good ends, which you can only hope (probably in vain) to achieve by another and yet another of those already innumerable Acts of Parliament, despite which every crime against sanitation is still paramount throughout the realm.' Whatever may be our present rate of progress, it is hardly to be expected that an agreement to this can be found while human nature remains as it is. Vested right and interest are too deeply ingrained and sanctioned to be readily displaced, and we must deal with the world as we find it. 'Benevolent absolutism' is not for an over-populated civilisation.

Two women were fined 10s. each and costs at the Gateshead Police Court, for exposing for sale a number of rabbits in a putrid state, and which Dr. Robinson, medical officer of health, stated were totally unfit for human food.

THE REGISTRAR-GENERAL'S I QUARTERLY RETURN.

By J. HAMPDEN SHOVELLER.

THE Registrar-General has just issued his quarterly return of marriages, births, and deaths in England and Wales. The statistics relating to marriages for the second quarter of the year, while relating to births and deaths are for the three months ending September last. The marriage-rate showed a marked increase upon the rate recorded for the second quarter of last year; the birth-rate was the average, while the death-rate, owing principally to the excessive fatality of summer diarrhoea, exceeded the average. The mean temperature for the quarter at the Royal Observatory, Greenwich, was 62°·7, and was considerably above the average for the corresponding periods of 112 years. The rainfall amounted to 4·53 inches, which was 3 inches below the average amount in the corresponding periods of 68 years.

During the second quarter of 1884 the marriages of 107,278 persons were registered in England and Wales, equal to an annual rate of 15·8 per 1,000 of the population, estimated by the Registrar-General to be rather more than twenty-seven million persons. This marriage-rate exactly corresponds with the average rate in the same quarter of the preceding years 1874-83, but exceeded by as much as 1·4 per 1,000 the rate recorded in the corresponding quarter of last year.

The births registered in England and Wales during the third quarter of this year were 2,100,000, corresponding to an annual rate of 33·0 per 1,000 of the estimated population. This birth-rate was 1·0 per 1,000 below the average in the corresponding quarter of the ten preceding years 1874-83. In several counties the birth-rates last quarter were: 26·7 in Herefordshire, 27·2 in Westmoreland, and 27·8 in Sussex, to 37·4 in Monmouthshire, 40·5 in Nottinghamshire, and 40·5 in Durham. 225,454 births registered in England and Wales during the quarter under notice exceeded the average by 90,776; this represents the natural increase of the population. It appears from returns issued by the Board of Trade that 87,523 emigrants embarked during last quarter from the various ports of the United Kingdom at which emigration offices are stationed. Excluding foreigners, and distinguishing those whose nationality was undistinguished, the emigrants of British origin were 72,631, including 48,414 English, 6,339 Scotch, and 17,878 Irish. The proportion of emigrants last quarter to a million of the respective populations of the three divisions of the United Kingdom were 1,784 from England, 1,784 from Scotland, and 3,610 from Ireland. Compared with the corresponding quarter of 1883, the proportion of emigration last quarter showed a decline in each of the three divisions of the United Kingdom.

From returns published by the Local Government Board it appears that the average number of paupers relieved on the last day of each week in the quarter ending September last was 682,057, of whom 168,076 received indoor and 513,981 outdoor relief. The proportion of the population in receipt of pauper relief showed a further decline from the corresponding quarters of the preceding years.

The deaths of 134,678 persons were registered in England and Wales during the third quarter of 1884.

ual to an annual rate of 19.7 per 1,000 of the population. This rate was 1.1 per 1,000 the average rate in the corresponding periods in years 1874-83, and considerably exceeded as recorded in any of the three preceding quarters, which were 16.8, 17.8, and 16.8 respectively. This excess in the death-rate was mainly due, as above stated, to the usual fatality of summer diarrhoea. In the counties the rate ranged from 13.5 in West-1, 14.4 in Oxfordshire, and 14.8 in Dorset-2 22.3 in Nottinghamshire, and 23.3 in Yorkshire and in Lancashire. In the principal districts, comprising the chief towns, and containing an estimated population of more than sixteen of persons, the rate of mortality last quarter 8 per 1,000; in the remaining and chiefly population of about ten millions and three- the rate was 16.5. These urban and rural rates respectively 1.3 and 0.5 per 1,000 below age rates in the ten preceding corresponding . In equal numbers living, the deaths were urban to 100 in the rural population. In twenty-eight great English towns, including and having an estimated population of more than millions and three-quarters of persons, the registered corresponded to an annual rate of 1,000, which was 1.0 above the general urban while the death-rate in London did not ex- 9, it averaged 24.3 per 1,000 in the twenty- provincial towns, among which it ranged from Bristol, 17.1 in Brighton, and 18.0 in Derby, Bolton, 27.5 in Liverpool, 28.6 in Leicester, in Preston. The rates of mortality at dif- ges in the twenty-eight towns showed the

usual wide divergencies; the death-rate among infants, measured by the proportion of deaths under one year of age to 1,000 births registered, ranged from 161 in Bristol to 424 in Leicester. The rate of mortality among persons aged between one and sixty years did not exceed 8.2 in Brighton, whereas it was equal to 15.9 in Liverpool; and among persons aged upwards of sixty years the death-rate ranged from 44.4 in Brighton to 86.4 in Bolton.

The 134,678 deaths in England and Wales included 43,143 of infants under one year of age, 62,184 of children and adults aged between one and sixty years, and 29,351 of persons aged upwards of sixty years. Infant mortality was equal to 191 per 1,000 births, and considerably exceeded the average for the ten preceding corresponding quarters. In the twenty-eight towns the proportion of infant mortality averaged 242 per 1,000; it was 223 in London, but as high as 258 in the aggregate of the twenty-seven provincial towns, among which it ranged from 161 and 184 in Bristol and Huddersfield, to 335 in Norwich, 355 in Bristol, and 424 in Leicester. Among persons aged between one and sixty years the rate of mortality last quarter almost corresponded with the average, while among elderly persons it showed a slight excess.

The deaths registered in England and Wales during the quarter ending September last included 28,748 which were referred to the principal zymotic diseases; of these, 18,630 were attributed to diarrhoea, 2,256 to scarlet fever, 2,355 to whooping-cough, 2,120 to measles, 1,982 to 'fever' (including typhus, enteric fever, simple and ill-defined forms of continued fever), 1,049 to diphtheria, and 451 to small-

pox. These 28,748 deaths were equal to an annual rate of 4.20 per 1,000, against an average rate of 3.65 in the ten preceding corresponding quarters. The zymotic rate in the twenty-eight great towns last quarter averaged 5.89 per 1,000, and ranged from 2.24 in Huddersfield and 2.83 in Bristol, to 10.25 and 10.61 in Leicester and Preston. In fifty other towns this zymotic death-rate averaged 4.58 per 1,000, while in the remaining or rural part of the country it was 3.21.

Diarrhœa was by far the most fatal zymotic disease in England and Wales during the quarter under notice; it caused no less than 18,630 deaths, equal to an annual rate of 2.72 per 1,000, against an average rate of 1.91 in the corresponding quarters of the ten preceding years. In the twenty-eight towns the highest diarrhœa rates were 6.48 in Nottingham, 8.32 in Preston, and 9.14 in Leicester. Among the fifty towns the highest rates of mortality from diarrhœa were 6.96 in Ipswich and 8.42 in Northampton. In the remainder of England and Wales, after excluding the seventy-eight towns, the rate did not exceed 1.98 per 1,000. The 2,206 deaths attributed to scarlet fever were equal to an annual rate of 0.33 per 1,000, which was little more than half the average rate. In the twenty-eight towns the rate of mortality from this disease was 0.41, but was equal to 0.98 in Leeds, 1.60 in Sheffield, and 2.36 in Cardiff. Among the fifty other towns the highest scarlet fever death-rates were 1.93 in Walsall and 3.00 in Wigan. The rate of mortality from whooping-cough was 0.33 per 1,000, and slightly below the average. In the twenty-eight large towns the death-rate from whooping-cough last quarter was 0.49, and was equal to 0.93 in Liverpool and 1.40 in Sunderland. The 2,125 deaths referred to measles were equal to a rate of 0.31 per 1,000, which slightly exceeded the average; in the twenty-eight towns the measles death-rate averaged 0.48, but was equal to 1.78 in Blackburn and 1.94 in Halifax. Among the fifty other town districts the highest rates of mortality from measles were 2.80 in Warrington and 3.92 in Accrington. The 1,982 deaths ascribed to 'fever' corresponded to an annual rate of 0.29 per 1,000, against an average rate of 0.35 in the ten preceding corresponding quarters. The fever death-rate in the twenty-eight large towns averaged 0.31 per 1,000, the highest being 0.53 in Plymouth and in Salford, and 0.58 in Blackburn. In the fifty other towns the rate of mortality from fever averaged 0.35 per 1,000, and was equal to 1.21 in York, and 1.23 in Colchester. A very serious outbreak of typhoid fever occurred at Kidderminster during the quarter, resulting in 46 deaths. The mortality from diphtheria considerably exceeded the average. Among the large towns this disease showed the highest proportional fatality in London and Portsmouth. Of the 451 deaths from small-pox recorded in England and Wales during last quarter, 196 were registered in London, 153 more in the adjoining counties (nearly one-half of the latter being of London residents removed to the Metropolitan Asylum Hospitals outside Registration London), 22 in Liverpool, 12 in Sheffield, 12 in Sunderland, and 56 in other parts of the country.

The causes of 123,123, or 91.4 per cent. of the 134,674 deaths in England and Wales last quarter were certified by registered medical practitioners; and 6,981, or 5.2 per cent., by coroners in inquest cases. The causes of the remaining 4,574, or 3.4 per cent. of the deaths, were uncertified. In London

the proportion of uncertified deaths was only 1 per cent., whereas it averaged 3.8 in the rest of England and Wales. In the twenty-seven large port towns the proportion of uncertified deaths was 2.9 per cent., and ranged from 0.6 and 0.8 in Southampton and Nottingham to 5.4 in Halifax and Oldham.

THE SANITARY RECORD

NOVEMBER 15, 1884.

—o—

The Editor will be glad to receive, with a publication, announcements of meetings, proceedings, and abstracts or originals to be read before the members of any sanitary or association.

Local Authorities throughout the country would confer a favour on the EDITOR of the SANITARY RECORD if they would forward all published documents relative to Water Sanitation, and Health matters generally, to come under their notice. He would be glad to receive reports from Engineers on works, Sewerage Projects and Domestic Sanitary Improvements for notice, commencing with an illustration.

WATER RATES.

DISPUTES between the London water companies and their customers are now of frequent occurrence, and, judging from the reports which appear in newspapers, it seems as though much time and money is expended. The time of the police-courts is often taken up in deciding questions as to the rateable value of premises supplied with water, though it may seem a hardship both to the ratepayers and to the parties concerned that such questions should have to be decided there, though it is clear that magistrates are the proper tribunals to decide them.

Some ratepayers, however, who from their position might be expected to know better, do not think that they have only to state that they make a complaint against a water company in order to obtain a judgment in their favour. One gentleman, for instance, who occupied stables as a dwelling-house, and presumably, therefore, was a person of some means, is reported to have obtained a summons against a water company, which they had ceased to give a constant supply of water, and substituted an intermittent supply. He made the application himself, and evidently without any legal advice or assistance, for he had not ascertained whether there was any provision in the Waterworks Act obliging them to give a constant supply, and seemed astonished when he was told by the magistrate that the general Acts enforced such an obligation. The above case may be taken as a sample of many others which are of constant occurrence.

ere people fancy that they have a grievance water company and immediately rush into a summons, or into print in a letter to the without taking the trouble to ascertain their complaint is well founded. As regards ly by correspondence, we must leave that oked after by the editor of the journal to : letter may be sent ; but, as regards appli- o police-courts, the applicants should re- hat frivolous applications are a waste of e and a hindrance to the business which occupies the courts. It may not be always o insist that a ratepayer shall consult a fore commencing legal proceedings against ompany, though, as the law to be applied ed in a number of rather confused statutes, be generally advisable for him to do so ; ink an educated man may reasonably be to read for himself and try to understand es under which he wishes to take proceed- re he brings his case before a court. There ver, been many cases in which the result me being, at any rate, for notice of appeal ally been given) has shown that the com- s right in objecting to the claim. A case me recently before the magistrates at l has raised a question which, so far as we erved, is a new one in the controversy, whether the companies are entitled to the annual value, not of the dwelling- plied, but also of its appurtenances. In in question, they had included a stable and the assessment (as no dqbnt they are in the poor-rate assessment), but the es thought it was absurd to include them oses of water rate, and struck them out. o refused leave to appeal. As far as we e from the short report we have seen, the was right ; but the question of what is to ed in the premises liable to water rate, is h, sooner or later, will have to be decided rt of Appeal.

ajority of cases which have been reported o special comment. The companies have, , in some instances been shown to have cessive and illegal charges for water in and it is asserted that they make such still. After the judgment in Dobbs's case that the assessment on which they were to charge was lower than that for which tended, they naturally enough attempted to for the diminution of income so caused ng their rates and making the maximum to which they were legally entitled. For ose, as many of our readers will remember, ed papers of interrogatories to be answered holders, so as to give themselves the mate- which to reassess the properties within icts. Some of these interrogatories were , but the bulk of them were probably d to the waste-paper basket. The com- plain that this has rendered their task of ment unnecessarily difficult. However, h information as they could obtain, they ised their assessments, and while charging rateable and not on the gross value of ises supplied, have in many cases raised ble value so considerably above what it ially as actually to increase the rate

When they have so revised them, they t notices to the ratepayers telling them of

the alterations and demanding payment according to the increased rate. In spite of certain letters which have appeared in the *Times*, we have no doubt that such notices were sent out in due course, though, like other circulars, they were very likely never read by the persons to whom they were addressed. As the notices were in many cases not attended to, and the increased assessment of the premises was not challenged, the companies have as a matter of business attempted to get their rates paid, and have in some cases cut off the water-supply when the money was not forthcoming. This conduct is complained of by those whose supply is cut off as harsh and unfeeling ; but the companies are empowered by section 74 of the Waterworks Clauses Act, 1847, to cut off the supply if water rates are not paid at the regular times of payment thereof, and unless they have exceeded their powers, it is useless to complain of their conduct. They are corporations, and as such are proverbially not influenced by human feelings. Whether the power of cutting off water is one which they should possess is another question, and it may well be that this power should not be given to the companies themselves, but should only be exercised by a court of summary jurisdiction. Such an alteration in the law has been proposed, and in the interest of the health of the community it might well be made. In the meantime it is well to remember that the companies have the right to cut off the supply if their rates are not paid, and that the fact of there being a dispute as to the valuation of the premises is not a sufficient ground to prevent their exercising their right. As was recently said by the vacation judge, on an application for injunction to make the East London Company restore the supply where it had been cut off, 'an interference with their statutory rights might cause mischief and wrong to them which it would be difficult to measure, while the inconvenience to the ratepayer was merely that he would have to pay a few shillings additional rates, with the certainty of the money being subsequently returned by order of the court if he was right in his contention.' Wherever, therefore, a householder is dissatisfied with the valuation put upon his premises by his water company, his proper course is to pay the amount claimed *under protest*, and, if he thinks his case good enough, to apply to a court of summary jurisdiction (*i.e.* to the nearest police-court) to have the value of his premises determined. The valuation for the poor-rate is a guide as to the figure at which his premises should be assessed, but it is not necessarily the value at which the magistrate will arrive. If the value put by the water company is much in excess of the poor-rate valuation it may be worth while to appeal to a court ; but if it is only slightly so, it will probably be better to put up with a rate slightly in excess of what the householder believes to be the right one, for even if he succeeds in reducing the charge it does not follow that he will get the costs of so doing, and the expense and trouble incurred may be greatly in excess of the reduction which he obtains.

FEEDING-BOTTLES.--Dr. Blackett, medical officer of health to the Brandon Local Board, ascribes much of the infantile sickness and mortality in the county of Durham to the common use of the feeding-bottle, when used for condensed milk. For want of sufficient cleaning the mowhpieces of the bottle are often half choked with clots of acidulated milk, while the tubes are lined with fungoid growths, teeming with minute insect life.

THE COCK-CROWING NUISANCE.

THE Nuisances Removal Act of 1855 (which is still in force as regards the metropolis, though elsewhere it has been superseded by the Public Health Act, 1875) contains a section, 13, which empowers justices by their order (a) to require the owner or occupier of premises which are in an insanitary state to provide sufficient privy accommodation, means of drainage or ventilation, or to make safe and habitable, or to cleanse, pave, whitewash, disinfect, or purify them or such part thereof as the justices may order; or (b) to require him to drain, empty, cleanse, fill up, amend or remove an injurious pool, ditch, gutter, watercourse, privy, urinal, cesspool, drain, or ashpit, which is a nuisance or injurious to health, or to provide a substitute for that complained of; or (c) to carry away any accumulation or deposit which is a nuisance or injurious to health; or (d) *to provide for the cleanly and wholesome keeping of an animal kept so as to be a nuisance or injurious to health, or, if that is impossible, then to remove the animal.* The Public Health Act, in sects. 91 *et seq.*, contains similar powers. It is obvious to any one who looks at the Acts and considers their scope, that these powers were intended to provide a summary means of getting rid of nuisances which might be prejudicial to public health; but that they do not deal with acts or omissions which, though coming within the legal definition of a nuisance and liable to be dealt with at common law, are not nuisances injurious to health. This is not only the meaning which one would naturally place on these sections, but it is that which has been decided to be the law. For instance, it has been held that justices have no power summarily to prohibit the continuance of a nuisance caused by continual dripping from a railway bridge on to a road, though that is, no doubt, a nuisance which might be remedied by the more expensive and more dilatory process of an indictment.

The portion of the above section relating to animals obviously was intended to apply to such places as pig-styes or overcrowded and insanitary cow-houses or stables, and it has been held that it does empower justices to deal summarily with them. Recently several attempts have been made before Metropolitan police magistrates to extend its operation to cases of nuisance caused by the keeping of noisy animals, generally crowing cocks, and the newspaper reports show that different magistrates take different views of their powers. Mr. Paget (*see* SANITARY RECORD for May 15, 1884, p. 554) and Mr. Barstow seem disposed to think that they can order the animals to be removed or destroyed in cases where satisfactory medical evidence is forthcoming to show that the health of any person has been injuriously affected by the noise: and there may, no doubt, be such cases, especially where the person affected is nervous or an invalid. Mr. Partridge is reported to have doubted his power to deal with such a nuisance, though he eventually granted a summons; and Mr. D'Eyncourt in another case refused a summons, telling the applicant she might bring an action for damages in the county court.

Neighbours who are annoyed by noise are perfectly justified in adopting the most ready legal means of stopping the annoyance which they can find available; and, where they find a magistrate disposed to entertain their complaint, may be able to get the nuisance abated summarily. If, however, the owner of the noisy bird or dog should object to

the jurisdiction of the magistrate to interfere, and should think it worth while seriously to fight the question, to the extent of an appeal if necessary, we have no doubt that it would be held that the nuisance caused by keeping a noisy animal—though it may in extreme cases be really detrimental to health—is not a nuisance which can be dealt with summarily under the Nuisances Removal Act or the Public Health Act. The persons who suffer annoyance, if the annoyance is substantial, have their remedy by action; and, if they wish to avoid expense, can bring the action in a county court. If a case is made out for it, either the county court or the High Court can grant an injunction to prevent a repetition or continuance of the nuisance, and would no doubt do so. The majority of the complaints which have been made to magistrates have probably been trivial, and if such complaints are kept out of court altogether so much the better for everyone; if the complaint is substantial, a police court is not the proper tribunal to settle it.

NOTES OF THE MONTH.

PREVENTION IS BETTER THAN CURE.

MISS BARNETT, of the National Health Society, 44 Berners Street, W., has started on another lecturing tour in the provinces. Manchester, Carlisle, Keswick, Workington, Cockermouth, and many other towns are to be visited. Her subjects are likely to prove attractive at a time when sanitary precautions are more needed than usual. 'How to Oppose the Cholera,' 'Prevention of the Spread of Infectious Diseases,' 'Air and Ventilation,' 'Good Food,' 'Sensible Dress,' 'Management of Infants,' and kindred subjects, are all treated in a simple practical manner. It would be a great advantage to the working population if such teaching could be constantly and thoroughly carried out in every town and village of the United Kingdom, so that the motto of the society—*Prevention is better than Cure*—should become a principle constantly carried out in practice.

THE VENTILATION OF SEWERS.

A REPORT was lately presented to the City Commissioners of Sewers by the Streets Committee relative to the suggestion of Mr. J. S. Scott:—'That in all instances where new houses are being erected the Commissioners of Sewers place themselves in communication with the building or other owner, and treat with him or them for the construction of a proper ventilating shaft in the chimney-breasts of party or other walls for the purpose of ventilating the sewers, carrying the ventilating shafts well above all adjoining roofs.' It was also stated that many years must elapse before this proposal could be carried out to an extent sufficient to have any practical effect, although the engineer explained that at the present time the Commissioners were always willing to place ventilators against the fronts or sides of houses wherever the owners allowed them to do so. The committee recommended that the suggestion be adopted, and it was determined to do so. Upon a former occasion (SANITARY RECORD, Aug. 15, p. 64) we commented upon the suggestion, and mentioned certain facts to be borne in mind; but as the provinces have carried out the same

ideas to a great extent, we may refer to an exhaustive report by Mr. E. Buckham, the borough surveyor of Ipswich, who in the earlier part of the year obtained valuable particulars of the working of the system in various large towns and manufacturing centres. According to his report, compiled from the surveyor's and engineer's information, the plan generally adopted is by an open man-hole and lamp-hole covers level with the street surface, supplemented in many towns with vertical iron pipes carried up in suitable positions on buildings and by factory chimney-shafts. The distance between surface-ventilators is given in some cases as low as forty yards and in others two hundred yards apart. In the case of the city of Coventry 1,500 vertical shafts of piping have been applied. They are also being extensively used at Great Yarmouth, and applied to the ends of small sewers in back roads or passages. These upright pipe-ventilators in many cases are reported not to have reduced the smell from the surface manhole-grates nearest thereto to the extent desired. Although in many cases the effect has not been what was expected, in other towns the result is spoken of as most satisfactory; in many towns referred to the plan has not been tried, for the reason that the ventilation from the surface-gratings is considered satisfactory. At Eastbourne the report is that vertical pipes have been tried, but with no effect in reducing smells from surface-ventilators; on the other hand, the surveyor of Bournemouth says that since the system of upright pipe-ventilation has been completed the complaints of smells coming from road grates have nearly ceased. At Gloucester, Yarmouth, Leeds, &c., also, there have been—considering the small number fixed—good results, but at Hove the returns are unsatisfactory. Improved exhaust-cowls for creating an upward current in the vertical pipes have only been applied in a few instances, the general opinion being that better results are obtained without them. In reply to inquiry whether in cases of complaint of nuisance arising from surface-ventilation upright pipes had been fixed near thereto with a view to its abatement and the closing of the street ventilator, it is found that in very few cases have openings been closed on such complaints; the rule has been to make more openings either at the street level or by vertical pipes. Hove and other towns report that the ventilators are never closed under any pretext whatever. In some cases the upright pipes have reversed the action of the openings in the street by causing a down-current in the one nearest thereto. At Bournemouth this was so, but from Carlisle 'some have acted in this way'; but generally the current is up. At Croydon a down-current was clearly shown, as ascertained before and after by anemometers. The surveyor of Gloucester states that the fixing of vertical shafts near to the sewer openings will not create a down-current, unless the 'sum of their sectional areas exceeds that of the two street vents between which they are placed, or the maximum sectional area of the air-space in the sewer itself, whichever happens to be greater.' At Yarmouth the vertical shafts affected the street openings to a distance of thirty yards; the same result has been noticed at Hereford, particularly in those cases where exhaust cowls have been fixed. Public sewers have been connected to tall chimney shafts in some places, and at Bolton the results are reported as good. At

Leicester twenty-five shafts have been applied, and the Corporation are extending the system; but from Sunderland they are not a success. Mr. Buckham, who has thus had great opportunities of forming a reliable opinion, has recently stated: 'I think, on the whole, ventilation by open gratings, level with the street surface only, to be a mistake; they should be accompanied with a system of upright shafts; the total areas of such shafts should exceed the areas of the street gratings; the result would be that there would then be a down-draught in the street openings and an up-current in the shafts. I am now acting upon this principle in Ipswich with the most satisfactory results.' It is highly desirable that the City Commissioners of Sewers should carefully consider the probabilities before they define any hard and fast rule, and the experience already gained cannot fail to be of the utmost assistance.

THE ALLEGED INCREASE OF DRUNKENNESS IN BIRMINGHAM.

It may be remembered that during the recent inquiry into the sanitary condition of Birmingham and the dwellings of the poor, much stress was laid by some persons upon the prevalence of drunkenness in that town, and the temperance party sought to show by statistics and evidence of facts of everyday occurrence that much of the poverty and wretchedness existing in some parts of the town was due to the great temptations placed in the way by the large number of licensed houses. A deputation of the temperance party waited upon the authorities to urge the consideration of remedial measures, and the allegations then made were replied to in detail by the Licensed Victuallers' and Retail Brewers' Associations. The result was the appointment of a special committee by the borough justices to consider the whole subject. This committee have presented their report, and at a meeting of the justices a few days since it was unanimously adopted. The committee state that, after considering the returns of the chief constable, they found that there had been a considerable increase in the number of charges of drunkenness during the past two years as compared with the numbers in previous years; but that this increase, in a large degree, is attributable to the greater vigilance on the part of the police. There was not evidence sufficient to justify the statement that drunkenness was on the increase in the borough. After hearing the views of the chief constable as to the alleged undue proportion in the number of cases of drunkenness and the number of convictions for permitting drunkenness, or for selling drink to persons whilst drunk, the committee personally examined several of the divisional superintendents of police, and returns of the charges were produced, showing the result of the prosecutions. There was no doubt that the absence of convictions in many cases was due to the fact that the offenders were charged with permitting drunkenness to take place on licensed premises, in which case the law required knowledge on the part of the landlord to be proved. The committee therefore recommend that in future instructions should be given to the chief constable to prefer an information (where the evidence warrants it) for selling drink to persons whilst drunk, in which cases it is not necessary to show that the landlord knew of the drunken state of his customer when he supplied him with drink. The superintendents believe there is an increase in the number of cases of selling drink

in brothels and unlicensed premises, and they attribute this to the inadequate fines recently imposed on conviction. But the evidence showed that these houses are as well, if not better, conducted than those kept by the proprietors or tenants of the licensed premises; therefore they see no ground for recommending any interference in this respect, but were of opinion that the system at present in force is perfectly satisfactory.

SEWER VENTILATORS.

AT the last monthly meeting of the Lanchester Local Board, Mr. Joseph Walton, a butcher, made a complaint of the nuisance arising from the terrible stench from a sewer ventilator which had recently been placed near his shop, to the great deterioration of his meat and injury to his trade. Other residents in the same neighbourhood had complained bitterly of the nuisance to the inspector, but had not received any reply. After an animated discussion a committee was appointed to inquire into the matter with a view to a remedy.

PAYMENT FOR HOSPITAL ISOLATION.

A CASE was tried in the Salford County Court a week or two ago which illustrates in a very forcible fashion how a narrow conception of municipal duties and responsibilities hinders effective action for the control of infectious disease. The Swinton and Pendlebury Local Board had sent a child into the local children's hospital, whilst suffering from typhoid fever; at least they persuaded the mother to let the girl go. The Local Board was charged six guineas by the hospital authorities for maintenance of the child, and this sum they tried to recover from the mother. The woman stated in Court that her husband's wages had only averaged twelve shillings per week for the previous fortnight, as he was on short time. The action was commenced under section 132 of the Public Health Act 1875, which enacts that any expenses incurred by a local authority in maintaining in a hospital, &c., a patient who is not a pauper shall be deemed to be a debt due from such patient to the local authority, and may be recovered from him at any time within six months after his discharge from such hospital, &c., or from his estate in the event of his dying in such hospital. The patient being a child under age, the Local Board brought its action against the father, but Mr. Russell, Q.C., held that the action should have been brought against the patient according to the section, but in this case, the patient being under age, the board was without a remedy.

This version of the law is a somewhat novel one, and if, as is stated, the Local Board appeal against it, would probably be upset by a superior court. But outside altogether of the technical legal point, the case appears to us to present points of general interest, as touching a matter of general policy. Was the Local Board wise in dragging this poor woman into the County Court in order to recover from her expenses which they had persuaded her to incur, and which represented some two months' wages of her husband? It would no doubt be a dangerous experiment to ostentatiously throw open the infectious wards of a hospital to all and sundry, free of charge in every case; but the repayment of expenses of maintenance in such a hospital ought to be looked upon as the exception rather than the rule, and we are convinced that that authority acts

most wisely in the general interest of its constituents which makes the isolation of infectious cases in a hospital as easy and as little burdensome as possible to the individual. The primary concern of the authority should be to stamp out disease; the payment of the burden of the expenses incurred should be a secondary matter.

'SWEEP! SWEEP!'

THE faith of the public, in the ability of metropolitan police magistrates to remedy any inconvenience which they may be subject, seems boundless; they only do they apply to them to get rid of the nuisance caused by their neighbours keeping noisy a place for which there may be some apparent justification in the somewhat obscure words of a section of the Act of Parliament, but a gentleman is reported to have recently applied to Mr. Cooke at Marylebone to abate a noise over which, as far as we can see, the magistrate had no jurisdiction whatever. The complaint was that a man employed by a club would persist in making the early morning hideous and disturbing the rest of the neighbourhood by loud cries of 'Sweep!' This conduct is no doubt annoying, as the utterance of most cries is, but we have not been able to discover if it was an offence cognisable in a police-court. The persistent making of any noise in an inhabited neighbourhood may amount to an actionable or an actionable nuisance. There is an old case of the King v. The Defendant, which is reported in Strange's Reports as follows: 'The defendant was convicted on an indictment making great noises in the night with a square trumpet, to the disturbance of the neighbourhood, which the Court held to be a nuisance, and the defendant 5/.' There are also many cases in which persons aggrieved have successfully brought actions in cases where they were seriously annoyed by noise. Magistrates have, however, no jurisdiction over such matters except such as is given by statute. In the metropolis they have power to impose small fines for such matters as musicians refusing to desist when desired by the householder to do so, or as 'wantonly disturbing any inhabitant by ringing a door-bell without excuse,' or, again, 'blowing any horn or using any noisy musical instrument for the purpose of annoying people together or of announcing any show or entertainment' (which latter power might perhaps be successfully invoked against the Salvation Army). These powers, however, obviously do not include the cry of the sweep; and, as far as we can see, persons disturbed by him must either indict him or bring an action against him, or else make use of their minds to put up with the disturbance. Some persons under their private Acts possess power to make by-laws, and we believe have made by-laws for the purpose of prohibiting or regulating street sweeping. Where this has been done there is, of course, the power of summarily imposing a small penalty on persons whose case such by-laws are infringed. But elsewhere the only remedy available is that which, as we have pointed out, is afforded by the common law. Persons seriously think that further powers of interference are needed, they must ask Parliament to give them. Such powers would, however, be wanted for the purpose of dealing with trivial nuisances, which are beneath the notice of any inferior Court, and which we think may well be left alone.

POISONING BY SHRIMPS.

larm has been recently created by a paragraph which has gone the round of the papers, in account of the poisoning of sixty-nine from eating shrimps, on September 21. The paragraph is based upon a report to the Sanitary Authority by their medical officer of health. According to this the sufferers lived in houses in Northdown, Margate, and nearly taken ill from six to twenty-four hours after eating of the shrimps, the symptoms being a cold, vomiting, cramp, and exhaustion. In the case of two women the attack seems to have been on labour, and one of these died, her death certified as puerperal fever. So many being taken almost simultaneously a common cause was obvious, and none could be discovered save the shrimps. At every house (with two exceptions) where these shrimps were delivered, those who ate them were taken ill. In one of the two houses for the exception the purchaser threw the shrimps away, and in the other the shrimps were bought raw, cleaned and boiled by the consumers. None of the shrimps which proved so unwholesome could be traced for examination, nor the water in which they were boiled, and as the pan used was an iron one there was no evidence of metallic poisoning. The reporter points out that the shrimps were caught 'near the outfall of the Margate sewer,' and that the 'shrimps, there could be no doubt, were out of season, and they were, therefore, not fit to eat.'

The family who escaped are stated to have been the out-of-season-state of the shrimps, and they had to cleanse them of what appeared to be a parasitic attachment.

The Town Council of Margate having had their attention drawn to the matter, instructed their medical officer of health to make full inquiry and report. This report, dated Oct. 14, is now before the Council. In the shrimps in question it appears were caught round between Nayland Rock and the Jetty 'on the shore,' the man who took them stating that 'he caught shrimps in the same place for the last two years, and that he has never known them to be poisonous or to produce injurious results. He fishes at the distance of ground he was fishing on a quarter of a mile from the outfall of the town sewer.'

Another man was shrimping alongside him on the same ground. Independent testimony was that no stale or other shrimps were mixed with the shrimps caught on Saturday night. A relative of the man who caught and sold the shrimps stated she boiled some for her own use 'in the ordinary way and without any cleansing.' Her husband and children, as well as herself, partook of them, and sustained no ill effect. In two adjoining houses, with the same water-supply, the one who had eaten part of the shrimps boiled by the other who caught them suffered severely. The shrimps caught on the same ground on the same night were boiled in the ordinary way and did not affect a single individual suffered in consequence of eating them. The conclusions the medical officer of Margate arrives at as the result of his inquiry are as follows:—

1. The shrimps boiled by Atwell on Sept. 20, and eaten by him on the following morning, caused illness at Northdown; that the shrimps when eaten were wholesome, and that they were not condemned by sewerage matter or infected with parasites; that it appears probable that the shrimps

became injurious during the process of boiling, some deleterious matter being either present in the pot or having been accidentally introduced therein.'

Mr. Henry Lee, late of the Brighton Aquarium, a well-known authority, writing to the *Times*, states that the assertion that shrimps are out of season in September is entirely contrary to fact. 'If they are out of season in any period of the year it is in May, as they cast their shells in April, and their newly-formed flesh is then flabby for a time.'

DISTRESS IN THE NORTH AND THE DEATH-RATE.

It is somewhat remarkable that the increase of the distress from want of employment in the north has been accompanied by a reduction in the annual death-rate. In Newcastle for the week ending Nov. 1, the average rate only reached 19 in the 1,000. During the same week Sunderland only showed an average of 20 in the 1,000, whilst the average death-rate of Hebburn for the month of October was only 14.3 per 1,000 per annum.

SANITARY ASSURANCE SOCIETIES' REPORTS.

A LAW case, which will probably be read with interest by the administrators of the numerous sanitary assurance societies that are now springing up in all parts of the country, was tried on October 22 at Glasgow, before Sheriff Substitute Rutherford. The circumstances which gave rise to the action were as follows:—The tenant of Huntington House, Haddington, applied to have the drainage and water-supply system of the house inspected and reported upon by one of the engineers of the Edinburgh Sanitary Protection Association, which was accordingly done on June 10 last. The report having by some means reached the hands of the proprietor, Mr. Robert Ainstie, he demanded an apology and that the association should withdraw the report. On the association, through their secretary, declining to do this, he brought an action in the Sheriff Court against Mr. James Thomson, C.E., the writer of the report, the Sanitary Protection Association, and their secretary and treasurer, demanding 500*l.* damages. Mr. Ainstie's pleas were:—1. That the statements in the report were false, reckless, and malicious, or without probable cause; and that the defenders were liable jointly and severally to the pursuer. 2. The sum sued for in name of reparation and solatium being fair and reasonable, decree should be pronounced as craved. The defenders, in reply, pleaded that the report was a privileged document, that it was substantially true, and that it was devoid of malice. This view was also taken by the sheriff, who in a somewhat sententious judgment, decided in favour of the association. The exact terms of the report on which the claims for damages were based are not definitely stated, but the report appears from the sheriff's 'opinion' to have been 'very complimentary to the sanitary arrangements in the interior of the house.' It is safe to say that in this respect it differs organically from most of the reports of sanitary engineers upon the drainage system of private houses.

THE BATTERSEA DUST YARDS.

IT is a curious reflection on our present impotent system of local government, and the apparently unlimited powers of the metropolitan water companies, that the objectionable and dangerous dust yards situated within a few yards of the reservoirs and filter beds of the Southwark and Vauxhall Company at Battersea should continue in active operation. Twelve years ago the late Mr. Netten Radcliffe described the nuisance as peculiarly injurious to the purity of the water, and evidence strongly emphasising this view is afforded by the health officers of the Wandsworth Board of Works, in whose jurisdiction the yards are situated. In a recent report these officers point out that the water-supply of the district, both as regards quality and quantity, is still unsatisfactory, and that that supplied by the Southwark Company contained relatively the largest amount of impurity, and was in the worst condition as regards turbidity and the presence of living organisms. This state of things has practically existed for the past twelve years, notwithstanding the reiterated protests of the local sanitary authority, the constant appeals to Sir Charles Dilke, and the promises of amendment on the part of those responsible for the nuisance. It is not so well known as it might well be that the company, by sect. 16 of their Act of last session, obtained powers to purchase this particular plot of land, and there exists nothing whatever to hinder them from doing so. The plea of poverty is ridiculous; but, even admitting that the exchequer of a company whose shares are selling at nearly 100 per cent. premium can be considered impoverished, there can be no excuse for the failure of the directors to adopt the simple and inexpensive plan of covering in the filter beds and reservoirs. It is to be hoped that the Local Government Board, who possess some sort of supervision over the doings of these companies, will take immediate steps for compelling the removal of an obvious danger to the health of many thousands of people.

NON-PAUPER PATIENTS IN INFECTIOUS HOSPITALS.

AN important step has been taken by the Metropolitan Asylums Board towards the unification of the arrangements for repressing infectious diseases which has for so long been a desideratum in the metropolis. At the meeting of the managers, held on October 25, an exhaustive report was presented by the General Purposes Committee on the question of the reception and treatment of non-pauper patients at the managers' hospitals. The report stated that the distinction having been practically abolished by the Legislature, and further hospital accommodation having been provided by the managers in accordance with the recommendations of the Royal Commission, the committee—upon the assumption that the managers, in maintaining the provision they have now made, and in making such further provision as they may hereafter find to be necessary, are not hampered or harassed by legal proceedings—were unanimously of opinion that the time had now arrived when patients suffering from dangerous infectious disorders should be admitted to the managers' hospitals upon the orders of the medical officers of health, as well as upon those of the district medical officers and relieving officers; and they accordingly recommended that the Local

Government Board be requested to place themselves in communication with the several local authorities of the metropolis with the view to issuing an order which shall empower the managers (in accordance with the terms of Clause 15 of the Poor Law Act of 1879) to contract with such authorities for the reception into the managers' hospitals of cases of dangerous infectious disorders other than those chargeable to the various parishes and unions. This report was unanimously adopted by the Board, and the matter is now receiving the attention of the authorities at Whitehall.

THE POLLUTION OF THE RIVER LEA.

THE condition of the lower reaches of the River Lea, to which we drew attention in our issue of September, appears to have at length aroused the serious attention of the dwellers upon its banks. The residents at Clapton have appointed a committee to investigate the matter, and this committee reported recently to a public meeting, held at Hackney, that, though unable to point to an immediate and distinct cessation of the pollution, they had reason to believe that a satisfactory result was but a matter of the comparatively near future, and the steps taken by the committee had at least been successful in securing the highest official attention to the matter. They had persistently urged the Hackney local authorities not to relax their pressure upon the Lea Conservancy to insist upon the rigorous application of the present notice, and to support that Board in a threatened application for an injunction against the Tottenham authorities. In the meantime, the committee recommended—1, that they should continue their efforts for the protection of the river; 2, that riverside committees should be formed to watch and report from week to week the condition of the river and for obtaining categorical evidence of continued pollution; 3, that petitions to Parliament should be prepared praying that increased powers should be given to the Lea Conservancy Board to more speedily and effectually protect the river from pollution. A resolution was also carried that, looking to the fact that Tottenham, Walthamstow, Leyton, and West Ham all discharge their sewage into the Lea, and seeing that those districts were greatly increasing in population, nothing was feasible short of an intercepting sewer to carry the sewage of those districts after treatment to the Thames at Barking, and that the Home Secretary be memorialised on the subject. Some means must evidently be taken to relieve the present deadlock; and it will be better that the riparian authorities of the Lea should move in the matter of their own free will rather than upon compulsion, which is only a matter of time under present circumstances.

LEAD POISONING.—In consequence of two young women having become blind by working at a lead factory on the Tyne, and thereby become a permanent burden on the ratepayers of Gateshead, the Board of Guardians have again memorialised the Local Government Board to urge on manufacturers the desirability of introducing mechanical appliances in the most dangerous processes of manufacture, particularly that of carrying white lead to and from the stoves. The manufacturers say that they have done all that the Government regulations require them to do, and the cases referred to are simply the result of their work-people culpably neglecting to avail themselves of the safeguards provided for them.

THE PUBLIC HEALTH

DURING OCTOBER 1884.

n temperature during the month of October at Observatory, Greenwich, was $48^{\circ}9$; it was $0^{\circ}7$ average October temperature in one hundred was $1^{\circ}5$ below that recorded in the corresponding of 1883. An excess of temperature prevailed days of the month, while on the other twenty it was below the average. The warmest day month was the 16th, when the mean was $56^{\circ}2$, and an excess of $5^{\circ}0$; the coldest day was when the mean was only $40^{\circ}5$, and as much below the average. Rain was measured with on twelve days during the month, to gate amount of exactly 1 inch, which was but more than a third of the average October rainfall in years. During the first ten months of this year it amounted to 14.5 inches, which was as much below the average rainfall in the same period of years. The sun was above the horizon during days during October, but only 59.3 hours of bright were recorded at Greenwich; this amount was not registered in the corresponding period of since 1880. The wind was very variable almost all the month.

twenty-eight large English towns dealt with by Registrar-General in his weekly return, which have had population of more than eight millions and others, 29,307 births and 17,223 deaths were during the five weeks ending the 1st inst. The , which had been 33.3 and 34.4 in the two months, further rose to 34.9 during October, and that recorded in the corresponding period of the two preceding years, 1882-83. In these eight towns the lowest birth-rates last month were Bradford, 28.8 in Brighton, and 30.7 in Halifax; other towns the rates ranged upwards to 39.9 in 40.6 in Sunderland, and 47.0 in Cardiff. The last month in London was 34.1 per 1,000, while it was 35.6 in the twenty-seven provincial towns.

Annual death-rate in the twenty-eight towns, in the two preceding months had been 24.2 and 1,000, further declined to 20.5 during October, and the decreased fatality of diarrhoeal diseases. , however, exceeded by 0.8 per 1,000 that recorded in the corresponding period of 1883. The lowest mortality last month in these towns was 15.9 in Bath. The rates in the other towns, ranged in the lowest, were as follow:—Birkenhead, 17.9; , 18.1; London, 18.6; Norwich, 18.7; Halifax, Bradford, 19.8; Derby, 20.1; Bristol, 20.2; , 20.5; Nottingham, 20.5; Plymouth, 20.5; , 20.9; Salford, 21.2; Hull, 21.4; Sheffield, 21.8; Oldham, 22.5; Wolverhampton, 23.0; Cardiff, 23.3; Leeds, 23.7; Sunderland, 24.6; Manchester, 24.6; Newcastle-upon-Tyne, Liverpool, 24.9; Bolton, 25.0; Blackburn, 25.2; highest rate during the month, 29.2 in Preshill the death-rate in London, as above stated, exceeded 18.6 during last month, it averaged 22.2 in the twenty-seven provincial towns. The deaths from all causes in the twenty-eight towns for five weeks of October included 2,244 which referred to the principal zymotic diseases, of which 1,141 were from diarrhoeal diseases, 345 from 'fever' (principally enteric), 320 from scarlet fever, 253 from whooping-cough, 226 from measles, 164 from diphtheria, and 102 from small-pox. These 2,244 deaths were equal to 1.1 per cent. of the total deaths, and to an annual rate of 1,000. This zymotic death-rate showed a decline from that in the preceding month, owing to a decline in the mortality from summer diarrhoea, and being below that recorded in the corresponding period of 1883. The zymotic rate in London

during October did not exceed 1.94 per 1,000, whereas it averaged 3.29 in the twenty-seven provincial towns, in many of which comparatively high death-rates from diarrhoea were recorded. The zymotic rates in the provincial towns ranged from 1.0 in Portsmouth, 1.2 in Brighton and in Plymouth, and 1.4 in Norwich, to 4.8 in Hull, 5.0 in Cardiff, 5.1 in Bolton, and 7.1 (of which 3.5 was due to diarrhoea) in Preston.

Diarrhoea was the most fatal zymotic disease in the twenty-eight towns during October. The rate of mortality from this disease, which had been 4.97 and 3.19 in the two previous months, further declined to 1.02 during October, but considerably exceeded the rates in the corresponding period of either of the two preceding years, 1882-83. The highest diarrhoea death-rates last month were recorded in Sheffield, Blackburn, Hull, and Preston. The rate of mortality from 'fever' (principally enteric or typhoid), which had steadily increased in the five preceding months from 0.22 to 0.38 per 1,000, further rose during October to 0.41, a higher rate than has been recorded in any month since November 1883. In London the fever death-rate did not exceed 0.28 per 1,000, while it averaged 0.53 in the twenty-seven provincial towns, among which the highest rates were 1.05 in Leeds, 1.11 in Salford, and 2.98 in Derby. The rate of mortality from scarlet fever was 0.38 per 1,000, and showed a slight decline from the rate in the previous month; this disease showed the highest proportional fatality in Preston, Sheffield, and Cardiff. The death-rate from whooping-cough, which had declined in the six preceding months from 1.10 to 0.36 per 1,000, further fell last month to 0.30, which, however, slightly exceeded the rate recorded in the corresponding period of last year. In London the rate of mortality from whooping-cough was only 0.16 per 1,000, while it averaged 0.42 in the provincial towns, among which the highest rates were returned in Nottingham and Sunderland. The death-rate from measles was 0.27 per 1,000, and corresponded with that recorded in the preceding month; in London the rate from this disease did not exceed 0.18 per 1,000, while it was equal to 1.23 in Cardiff, 1.36 in Preston, and 2.11 in Bolton. The rate of mortality from diphtheria showed a further increase upon that recorded in the two previous months; this disease was proportionally almost twice as fatal in London as in the aggregate of the provincial towns. During the five weeks of October 77 deaths from small-pox were registered in the twenty-eight towns, showing a considerable increase upon the number during September; of these, 64 were returned in London, 4 in Birkenhead, 3 in Sunderland, 2 in Liverpool, 2 in Hull, 1 in Wolverhampton, and 1 in Birmingham. Judged by the returns of the Metropolitan Asylums Hospitals, the prevalence of small-pox in London showed an increase during October. The number of small-pox patients under treatment in these hospitals, which had declined from 1,290 to 536 at the end of the four preceding months, rose to 580 at the end of October. The average weekly number of new patients admitted to these hospitals, which had been 73 and 84 in the two previous months, rose during October to 148.

The rate of infant mortality in the twenty-eight towns, measured by the proportion of deaths under one year of age to births registered, was equal to 160 per 1,000 during October, against 162 and 156 in the corresponding periods of the two preceding years, 1882 and 1883. While the rate of infant mortality did not exceed 130 in London, it averaged 183 in the twenty-seven provincial towns, among which it ranged from 101 and 119 in Portsmouth and Brighton, to 215 in Sunderland, 226 in Preston, 227 in Leicester, and 228 in Bolton.

The death-rate from diseases of the respiratory organs, judged by the metropolitan returns, was below the average during October. The weekly number of deaths referred to these diseases in London averaged 264, and the annual death-rate was equal to 3.4 per 1,000. In Liverpool the annual rate of mortality from these diseases was last month equal to 5.6 per 1,000.

The causes of 361 of the 17,223 deaths registered in the twenty-eight towns during the five weeks of October were not certified, either by medical practitioners or by coroners. These uncertified deaths were equal to 2.10 per cent. of the total deaths, which was below the average percentage in recent months. In London the proportion of uncertified deaths did not exceed 1.03 per cent., while it averaged 2.85 in the twenty-seven provincial towns, and ranged from 0.00 to 0.99 in Derby and Portsmouth, to 4.82 in Sheffield, 5.00 in Salford, and 5.12 in Liverpool.

Among the population living in the outer ring of suburban districts around London, estimated at rather more than a million persons, the annual death-rate during October from all causes was equal to 15.1 per 1,000, against 15.2 and 14.3 in the corresponding periods of 1882 and 1883. During the five weeks ending the 1st inst., 51 fatal cases of small-pox, 48 of diarrhoea, 31 of diphtheria, 26 of whooping-cough, 22 of measles, 19 of fever, and 16 of scarlet fever were recorded in the outer ring. These 213 deaths were equal to an annual rate of 2.1 per 1,000, which exceeded that recorded in the corresponding month of either of the two preceding years. The fatality of whooping cough and diarrhoea declined, but that of each of the other zymotic diseases showed an increase. The 51 deaths from small-pox registered in the outer ring were all recorded in the district of West Ham, and included 15 of London residents registered in the Metropolitan Asylum Hospital at Plaistow. Four fatal cases of diphtheria occurred in Tottenham sub-district.

NOTIFICATION OF INFECTIOUS DISEASES.

In the table on page 225 are published uniform statistics of sickness and mortality in twenty-seven of the thirty-nine sanitary districts in England and Wales wherein the notification of infectious disease is compulsory. The estimated population of the twenty-seven towns for which we are enabled to publish complete statistics for the month of October is about two-and-a-half millions of persons. The annual rate of mortality from all causes per 1,000 persons estimated to be living in these towns, which in the three preceding months had been 19.53, 23.41, and 22.55, further declined during October to 20.51. This decline in the death-rate was principally due to the decreasing prevalence of diarrhoeal diseases. In the twenty-eight large English towns dealt with by the Registrar-General in his weekly returns, the death-rate during October averaged 20.50 per 1,000, which was slightly below the mean rate in the twenty-seven towns in the accompanying table. The rates of mortality were last month considerably below the average in Barrow-in-Furness, Lancaster, Burton-upon-Trent, Edinburgh, Leek, and Halifax, while they showed an excess in Bolton, Blackburn, Accrington, and Preston. The death-rate from the eight infectious diseases dealt with in the table averaged 0.98 per 1,000 in the twenty-seven towns which furnished this information, and showed a considerable further increase upon the rates recorded in the two preceding months, which were 0.54 and 0.77 per 1,000 respectively. No death from any of these diseases was returned in Macclesfield, Reading, or Warrington, and only a single fatal case in Burton-upon-Trent, in Lancaster, and in Leek; while they caused the highest rates of mortality in Greenock, Hartlepool, Preston, and Derby. Small-pox caused 3 deaths in Birkenhead; scarlet-fever was proportionally most fatal in Rotherham, Greenock, and Preston; diphtheria in Dundee and Greenock; and enteric fever in Birkenhead, Blackburn, Preston, and Derby. Two deaths were referred to puerperal fever in Bradford. With reference to the notified cases of infectious diseases, it appears that the proportion of the population reported to be suffering from one or other of the eight diseases was 7.92 per 1,000, against 4.07 and 6.85 in the two preceding months. Only one

case of any of these eight diseases was notified in ton during October; in the other towns the per 1,000 of the population ranged from 3.60 in 3.81 in Accrington, and 3.89 in Stalybridge, to Edinburgh, 11.41 in Rotherham, 13.28 in Gree 32.02 in Derby. The exceptionally high rate in the last-mentioned town was due to an epidemic typhoid fever, no less than 206 cases of this disease being notified during the month. Thirty-two small-pox were notified in Birkenhead during scarlet-fever showed the largest proportional in Edinburgh, Derby, Reading, and Rotherham fever in Edinburgh, Blackburn, Preston, and typhus in Aberdeen; and diphtheria in St Greenock, and Dundee. Five cases of relapse were notified in Halifax during last month.

SPECIAL REPORTS.

SOCIETY OF MEDICAL OFFICERS' HEALTH.

T. ORME DUDFIELD, M.D., *President*

A MEETING of the Society of Medical Officers was held on October 17, 1884.

Mr. Hugh Stott, medical officer of health for Barnet, was elected a member of the society.

Dr. Frederick East, of 2 Clapton Square E. elected an associate of the society.

The president delivered an inaugural address on the Metropolitan Sanitary Administration, which will be in the SANITARY RECORD of Dec. 15.

At the conclusion of the address, on the motion of Bristowe, a unanimous vote of thanks was accorded Dr. Dudfield for his valuable address.

On the motion of Mr. Shirley Murphy and Mr. Corner, it was resolved that the address should be read and that a copy should be sent to each member and associate of the society, to the Local Government and to each metropolitan local authority.

The president then proceeded to present to the Northcote Vinen, in the name of the society, a solemnly engrossed copy of a resolution adopted at a meeting. The resolution was as follows:—

'At the annual meeting of the society, held on 1884, a letter was received from Dr. J. Northcote resigning his office of honorary secretary, which was unanimously resolved that the resignation be received with regret and that the best thanks of the society be given to Dr. J. Northcote Vinen, M.D., for the long and valuable services which he has devoted for a period of more than twenty years with manifest advantage to the interest of the society. By these presents the society desire to express to him their warm appreciation of his labours and sincere wishes for his future welfare and prosperity.'

In presenting this testimonial, the president read a brief résumé of the progress of the society since its foundation in 1856. He believed that of those present, Dr. Bristowe, and Dr. Conway Evans were the only original members; in 1863 they had only two metropolitan members and 17 other members, in twenty years ago. The association now numbered 210 and by the list laid before them that evening he believed the number would be 210 at the next meeting. All due in great measure to the excellent services rendered by Dr. Vinen, who he regretted was now retiring from the society. He had held so long. He knew every one would join him in sincerely hoping that they would long have Dr. Vinen amongst them as a member of the society.

In acknowledging the testimonial, Dr. Vinen said that the society had placed him in a position of considerable difficulty, for he did not know how to thank them adequately for the handsome way in which they had been able to acknowledge any services he might have rendered.

dered the society as secretary. Many changes had taken place since he was first elected to the office, when (as the president had stated) the society consisted only of metropolitan members; but as medical officers of health were appointed in the country, the society began to increase in numbers and importance until it soon took its position as one of the recognised societies of the metropolis. Dr. Vinen thought that in any acknowledgment made by the society of the services of the secretaries, too little had been bestowed on his colleagues and too much on himself. He had only to mention the names of those with whom he had been associated to show the influence they must have exercised for the good of the society. His first colleague was Dr. Buchanan, then Dr. Thomas Stevenson, afterwards Dr. Corfield and Mr. Shirley Murphy. The feeling had been growing on him for some time that it would be better for the interests of the society if he retired, and that the duties of secretary should be in younger and more active hands; but having performed the duties for so many years he felt some reluctance in resigning them. In conclusion, he stated that the testimonial would be regarded as a valuable heirloom by his family.

The society then adjourned.

THAMES POLLUTION.

A LARGELY attended meeting of the ratepayers and residents of the riverside town of Erith and the surrounding neighbourhood has been held at Erith, presided over by Sir Charles Mills, Bart., M.P., relative to the state of the River Thames, and the delay in the issuing of the Report of the Royal Commissioners on Metropolitan Sewage Discharge.

The meeting was addressed at some length by Sir Charles Mills, who dwelt upon the evils arising from the present polluted state of the river, which had been stated to be a national disgrace, and urged the desirability of selecting a lower site for the metropolitan outfalls.

W. Anderson, Esq., J.P., C. A. Streeten, Esq., Chairman of the Erith Local Board, and several other local influential gentlemen also addressed the meeting, and the following resolutions were unanimously passed.

1. That this meeting of ratepayers and residents of the parish of Erith, in public meeting assembled, whilst rendering to Her Majesty's Royal Commissioners on Thames Sewage Discharge their best thanks for the labours they have bestowed on the objects of the commission, beg to record their opinion that the delay in issuing their report as to the remedy to be adopted is much to be deplored, as the continued and increasing foul state of the Thames is such that thorough and speedy remedial measures should be applied forthwith; and this meeting begs that Her Majesty's Royal Commissioners will report to Her Majesty immediately—collectively or individually—as to the necessary sanitary measure or measures to be adopted for the purification of the Thames.

2. That this meeting, being in possession of the details of the proposed scheme of Sir Joseph Bazalgette to carry the sewage of the metropolis from Crossness to Barking, and thence to some nine miles below Gravesend, and there discharge it in its crude condition—beg to record that in their opinion any such scheme, if adopted, will be incomplete unless it provides for filtration and separation of the sewage matter, so as to insure a comparatively innocuous effluent water only being passed into the Thames.

3. That in the opinion of this meeting, pending the adoption and completion of any scheme determined upon for the disposal of the metropolitan sewage the most perfect and effective system of deodorisation should be employed to treat the sewage at Crossness and Barking before its discharge.

4. That the thanks of this meeting be accorded to Sir Charles H. Mills, M.P., for his kindness in presiding; and that copies of the foregoing resolutions be forwarded to Her Majesty's Secretary of State for the Home Depart-

ment, to Her Majesty's Royal Commissioners on Metropolitan Sewage Discharge, to the Metropolitan Board of Works, to the Port Sanitary Authority of London, to the Conservators of the River Thames, and to the Town Council of Gravesend.

THE AMERICAN PUBLIC HEALTH ASSOCIATION.

(FROM OUR SPECIAL CORRESPONDENT.)

THE American Public Health Association, the most representative and influential sanitary organisation in this country, held its twelfth annual meeting in St. Louis, Missouri, from Oct. 14 to 18, there being eight sessions. The President of the Association during the year past, and who presided over the sessions, is Albert L. Gihon, M.D., medical director in the United States navy. For two preceding meetings the interest in the Association seemed to be dying out, but at the last meeting there was an abundance of enthusiasm and a large attendance of members. There is, undoubtedly, something in the geographical location of the place of meeting, which affects the attendance materially. The members who attend most frequently are sanitarians from the Southern States, and if the meeting is too far north they stay away. This, mainly on account of the expense of travel; the distances are so great in the States, that railway fares are something of an obstruction to sanitary work of this character, for our American sanitarians will not go very far down into his private pocket to pay for advancing the public health. The Association is of a voluntary character, having active members, those who are engaged in sanitary work, and associate members, those who are taken in to defray the expenses. There was an abundance of papers, presented on various subjects, many being simply read by title for lack of time to devote to their consideration. It was decided to incorporate the Association under the laws of the district of Columbia. The treasurer's report showed a cash balance of 1,245.53 dol. in hand. There were three papers read on the habitations of the poor, no one of which presented any specially new feature. Dr. Geo. H. Rohé, of Baltimore, read a paper on the hygiene of occupation, basing his premises on a table which is here given. It shows the occupations by classes and the average age at death of 144,954 decedents in the state of Massachusetts, from May 1, 1843, to Dec. 31, 1874:—

TABLE.

Occupations.	No. of decedents.	Average age at death.
All classes and occupations.....	144,954	38.91
Cultivators of the soil.....	32,831	65.79
Active mechanics in shops.....	10,576	47.57
Inactive „.....	17,233	45.37
Labourers, no special trade.....	28,058	47.41
Factories, labouring abroad.....	7,035	37.99
Employed on the ocean.....	8,644	46.44
Merchants, financiers, agents, &c.....	15,965	48.96
Professional men.....	5,175	50.31
Females.....	3,343	39.75

A paper was read urging that it be made compulsory for labourers who were liable to have chips fly in their eyes to wear mica glasses, as is done in Germany. Another paper advocated the use of hospital cars on railways to prevent contact with contagious diseases. In the president's address, organisation was said to be the one thing needful in municipal sanitary reform. In a paper giving some results of a sanitary inspection of the schools in the state of Indiana, it was stated that forty-seven per cent. of the yards were not fenced, in 14 per cent. stagnant water was standing, and 30 per cent. of the school-houses had no proper means of ventilation. A paper was read urging cremation as a safeguard against epidemics. One of the most

portant papers was by Dr. Henry G. Baker, the secretary of the State Board of Health of Michigan, entitled, 'The relation of Depth of Water in Wells to the Causation of Typhoid Fever.' For a series of years the doctor has collected data concerning the depth of the ground water in the State at many different points. These data he has compared with the records of meteorological conditions, and with the records of sickness from typhoid fever. By his comparison he showed that deaths from typhoid fever were in many cases coincident with the low state of the ground water, and that these occur in very warm or very cold weather. From the evidence he believed that there was a relation between these conditions. The serious evacuations from cases of severe diarrhoea are probably the direct cause of typhoid fever, and in Michigan the fever increases every autumn immediately after periods when diarrhoea prevails extensively. A study of the relation closets bear to wells will reveal the cause, for when there is a low state of the ground water, there is a tendency for the fluids from the closet-vault to flow down into the well or water near the well. The dilution of water in wells when the ground-water is high explains the decrease of typhoid fever at those times. Typhoid fever can be prevented by stopping drinking contaminated water. Mr. Henry Lomb, of Rochester, made a donation of 2,000 dollars to the Association to be given in prizes next year for the best essays on the following subjects: Healthy homes and food for the working classes; the sanitary conditions and necessities of school-houses and school life; on disinfectants and individual prophylaxis against infectious diseases; appliances and means for saving life and for protection against injurious influences of some work and occupations on health. Prizes of 500 dols. each. The essays to be the property of the Association and to be ready April 5. The new officers elected were as follows: James E. Reeves, M.D., of Wheeling, West Virginia, president; Hon. Erastus Brooks, of Richmond, New York, first vice-president; Dr. Henry B. Baker, of Lansing, Michigan, second vice-president; Dr. J. Berrien Lindsley, of Nashville, Tennessee, treasurer; and an executive committee of six. The next meeting will be held in Washington in December 1885.

There was a meeting of the Conference of State Boards of Health at St. Louis on Oct. 13 and 14, separate from the Health Association. The most important work it accomplished was the adoption of a report on the subject of cholera, which stated that the three essential factors to the prevalence of cholera in this country as an epidemic are the importation of the disease by means of ships more or less directly from its only place of origin in India; unsanitary conditions favourable to the reception and development of the disease; persons sick with the disease at some of its stages, or things infected by such sick persons, to carry it from place to place. It further recites that, although State and local boards of health were never well organized as now, yet if cholera once secures a foothold in the country, inland quarantines are not easily successfully maintained. In view of a threatened invasion of cholera, and the constant danger from other causes, Congress is asked to maintain a system of medical attachés to all foreign ports where contagious diseases are liable to exist. As the Canadian provinces are so closely allied to the States in the danger, some system by which both countries may be uniformly protected is urged. It recommends prohibition of immigration from infected countries; it asks Congress to appropriate 500,000 dols. to be used in stamping out the disease and preventing its spread from State to State; and sanitary work is urged upon all cities. The Conference will meet in Washington in December next, and hopes to impress on the Government the importance of its suggestions.

The above sentiments being those of our leading health officials, it may be seen that cholera is fully expected in this country next year.

All seaport quarantine restrictions will be removed on Oct. 31.

An effort is being made—a very weak one, however—to have a sanitary exhibit at the great cotton and industrial exposition in New Orleans, which is soon to open.

THE TYPHOID EPIDEMIC AT KIDDERMINSTER.

THE outbreak of typhoid which has during the last few weeks wrought so much devastation in the busy little town of Kidderminster, continues to excite much attention from the medical and sanitary authorities of the district, and much uncertainty still prevails whether to attribute it to a contaminated water-supply, or to contagion arising from the escape of sewer-gas containing fever germs into the streets and into the houses. Up to the time the medical officer's monthly report for October was made up, there had been seventy-four deaths from the disease, forty-seven having occurred during the previous four weeks, while something like 800 cases have been reported. The mayor (Mr. D. W. Goodwin) declined to comply with the requisition which, as stated in last month's issue of the *SANITARY RECORD*, was presented to him to call a town's meeting to consider the question, and an open-air meeting was consequently held, at which his conduct in the matter formed the subject of criticism. A proposition was made to the meeting fully approving of the action of the medical men in the town in condemning the water-supply from the lower well, at the sewage pumping works, for use for domestic purposes, and this was passed, an amendment calling upon the Corporation to close the well and sink others in the upper parts of the town being lost. Another resolution was moved and seconded to the effect that the meeting was of opinion that the members of the Corporation had been too fully occupied in acquiring property of doubtful value, and had devoted too little attention to the health of the town. But it was not carried, an amendment being passed declaring 'that the members of the Corporation had done the best they could to stop the epidemic.' Dr. Parsons, the Local Government Board inspector, has paid a second visit to the town during the month, and has instituted a searching investigation into the sanitary condition of the place, making in some parts a house-to-house visitation. He also received a deputation of the townspeople, and suggested to them the advisability of forming a sanitary association or vigilance committee, with a view to assisting and strengthening the hands of the council. Some voluminous correspondence has also taken place on the subject in the local papers, from those who do and from those who do not understand the question. Mr. J. E. Stone contends that the water both from the upper reservoir and the lower well has been cleared from blame, that the 'sweating' from the sewage-pipe running close to the lower well was practically nothing, and that the outbreak is to be attributed to an intermittent rather than a polluted water supply, allowing sewer-gas to be sucked through the sink-traps into the pipes, where it contaminates the water when the latter is again turned on. His theory is an ingenious one, and as it bears out the only practicable solution that has yet been arrived at—viz., that sewer-gas is in some way to blame for the epidemic, it attracted a good deal of attention. It has to be remembered, however, that sewer-gas in itself, unpleasant and noxious as it may be, will not produce typhoid; nor would the quantity that would get into a house in the manner Mr. Stone suggests be sufficient to account for the widespread and serious nature of the outbreak. Dr. Horace Swete, medical officer at Droitwich, while agreeing with Mr. Stone in his main contention that the mischief was caused through the pollution of the water-supply with sewer-gas, applies the theory in a more practicable manner. Typhoid excreta have, he understands, been passing through Kidderminster sewage-pipes for some months past, so that there has been no dearth of germs, whilst the great heat of summer caused gas to be largely formed. This gas would easily carry with it these germs, which are infinitesimal in

work. The manual education of the plumber secured during his apprenticeship, and much work learned besides, but there was a great want of education, and the question was how this to be imparted. It must be derived more or less from the mere seeing and handling of lead would all its properties and applications, any more than the large of the bones taught the practice of surgery—the institution of the City and Guilds Institute, and various technical schools. There should be not only a written but an oral examination, besides a practical test of the capabilities of the metals. He would like to follow more or less closely the system of the National Health Society in the plumbing, which was inaugurated by Mr. Shaw; and would accord in the first year to any but those who passed the examination with commendable credit. It would repay the plumber for coming a long distance to receive such a course as it would place his thorough competency beyond

Mr. T. Mills (of the Technical College, Finsbury) rose on the same subject, in which he urged that education requisite for the plumber of the future should be divided into the following heads. Mechanical work of the trade; practical work of the trade; and theory of the trade. Under the first head he would include technical geometry appertaining to the trade, in-ut-tern-cutting, or the development of surfaces, the making of working drawings from dimensioned sketches, to be done by the student from models of appliances and fittings. The second head in-clude the manipulation of sheet-lead, elementary sheet metal work, and instruction in the various kinds of joints; the third head comprised instruction in the physics of the metal, with laboratory work, by the aid of lectures and experiments. This latter would include the properties and alloys, the composition of solder and the action of air and heat on molten metals. It might be expected that men who had reached middle age would have had family or other ties, would take up the instruction put forward by him as needful for the career of the future. By the very words 'of the young men' were necessarily indicated, and it was no heavy call on a young man to attend a course of instruction spread over (say) two years. When this was done, a plumber would be as much trusted and respected as he had been abused of late years.

Mr. V. Clarke, a teacher of plumbers' work under the City and Guilds Institute, read a paper in which he discussed the meaning of technical education was not understood by the London plumbers. No man in the trade by reading books or at evening lectures. Technical education, as commonly understood, was not experience, and would never take its place. At the time it was often asked, what was the good of a knowledge of technology? It might as well be asked, what was the good of brains? The plumber who knew of the nature of the metals he used would take advantage of protecting the public from injurious connoisseur matters, and would know what should be done for each special purpose. A knowledge of hydrostatics, however elementary, was of great value to the plumber. He had never known an architect who gave detailed drawings for the plumber to do the remedy for this was that the plumber educate himself, so that the architect would have to advise with him personally. The plumber would know how to make drawings, so as to be able to show them to those in authority. It was necessary also that the plumber should educate himself to prevent his being pushed about by sanitary engineers. The best solution of the problem was the establishment of trade scholarships, the munificence of the rich City companies, which should be opened in any place where a few plumbers gathered; but the plumbers themselves had not taken the subject as they might.

Mr. E. G. Mawbey (Borough Surveyor of King's Lynn), in a paper read by him, stated that it was frequently found more difficult to convince the plumber than the owner of the necessity for modern sanitary arrangements. Plumbers, instead of opposing, should, in their own interests as well as for the benefit of the public, support the suggestions of experienced surveyors and sanitary inspectors. There was not so much difficulty in securing the technical education of plumbers in large cities and towns as in small towns and districts. This might, however, in the latter cases be effected to a great extent by holding plumbers' district meetings for the reading and discussion of papers, and the medical officers, local surveyors, and sanitary inspectors might be invited to take part therein, and the papers, &c., printed and circulated. The example of the Sanitary Institute might with advantage be followed by instituting examinations for plumbers and granting certificates to competent men.

In the discussion which followed, Mr. Smeaton (London) maintained that the plumbers knew very well what they had to do. They had to get a living. A specification was put into their hands by a person who knew little about plumbing. The plumber was ordered to carry out his instructions and to mind his own business. The honest plumber was too often put on one side, and any one who could write on sanitary science came to the front. Competent plumbers only should be employed in connection with technical instruction for the trade.

Mr. P. J. Davies (London) said that what was required was a number of duly registered instructors of the plumbers' trade. There should be an examiner in each district, and then there would be no difficulty in getting good plumbers. He was certain that members of the craft would never tolerate licences.

Mr. W. P. Buchan (Glasgow) contended that no man could learn the plumbing trade out of the shop. When a journeyman he had often to refuse to answer the questions of clerks of works, when under the master's order he had put on 5 lb. lead piping instead of 6 lb. lead. A knowledge of drawing lay at the root of the whole question of the education of the workmen.

Mr. Matkin was in favour of licensing plumbers.

Mr. Scott-Moncrieff (London) thought that the meeting should do something in the way of passing a resolution in favour of technical education. The day had nearly gone by when any plumber could take refuge under the failure of other tradesmen in connection with the sanitation of a house.

Mr. Humphrey (Nottingham) considered that plumbers' work was not of the offensive character that should necessitate its being buried out of sight. The work should be open for inspection, and be thoroughly good work of its kind. The architect should be the ruling spirit in building work, but he should consult the men who had devoted their lives to particular branches of trade.

The chairman here suggested that some such resolution as the following should be passed:—

'That, in the opinion of this Congress, it is desirable that in future architects should not include plumbers' work in builders' contracts.'

This was received with great applause, and was proposed by Mr. Clutterbuck, who said they had a right to protest against builders taking every kind of business in hand. Contracts should be divided, and so should the responsibility. The plumber would then receive 10 per cent. more for his work and the public be better served.

Mr. Firth (Kensington) seconded the resolution.

Mr. F. C. Penrose (architect) expressed his adherence to the separation of the plumbing work from builders' contracts.

Mr. Lane opposed the resolution, believing that divided responsibility would end in no responsibility.

Mr. Wandsborough contended that the action of the architects in including plumbers' quantities in building contracts had done more than anything to damage the

trade. The architects would be serving the public better by conferring with practical men in their various spheres of work. If the work were divided it would open up facilities for the development of education, which masters at present could not afford to carry out.

The resolution was carried with one dissentient.

The next subject discussed was :—

'APPRENTICESHIP, THE DURATION AND CONDITION OF INDENTURES SUITED TO THE PRESENT STATE OF THE PLUMBING TRADE, AND TO THE MODERN SYSTEM OF TECHNICAL INSTRUCTION.'

Mr. W. R. Maguire (Dublin) read a paper, in the course of which he said that the apprenticeship of plumbers should not be reduced to a shorter period than seven years, as of old time. The object should be not so much to induce apprentices to come in, as to insure that when they went out they should take with them a well-taught, well-learned, and well-practised handicraft for public benefit. Payment to apprentices should be formed more in accord with their value to their masters, than was now the case. Even if paid little in the first year, there should be a tangible payment and steady advance of wages year by year. Employers being as different in character as workmen were, the Congress might frame some suggestions on the subject which would be accepted as a good guide by both employer and employed.

Mr. Frederick Fell (Worcester) followed with a paper on the same subject. Never in the history of the mechanical trades had so great a necessity existed for an apprenticeship of long duration and strict in its terms. Where the master confined his business strictly to plumbing, all that was needful might be learned in six years. He would like to see introduced into the indentures clauses compelling the apprentices to attend classes at properly constituted Science and Technical Schools, and to pass at least two examinations during their term. The first of these should be simple and mainly practical, and the second one of a more searching character. No tradesman should be allowed to assume the responsible position of master unless qualified to be one.

Mr. Smeaton in a paper contended that apprenticeship should be for at least five years, the most suitable time for which would be between the fifteenth and twentieth year. One or two evenings a week should be devoted to the study of the theory of plumbing, including drawing, geometry, water supply, heating, drainage, and the roofing of dwellings. The apprentice must be allowed, by mutual consent or arbitration, to have one master, and finish his term with another for the purpose of improving his knowledge of the trade. It would also be well if the indentures were endorsed as to the conduct and ability of the apprentice.

Mr. Scott-Moncrieff thought that five years would be a good period, with perhaps another two years as a term of probation in other workshops. He moved :—

'That, in the opinion of this Congress, it is desirable that the apprenticeship system should be continued, and modified, if necessary, to suit the improved course of technical education.'

This was seconded by Mr. Stolder, and agreed to.

The third question discussed was,

'THE ESTABLISHMENT OF METROPOLITAN AND PROVINCIAL BOARDS OF EXAMINERS OF PLUMBING WORK.'

Mr. P. J. Davies opened the subject with a paper, in which he advocated that a Metropolitan Board of Plumbers should be established, with head-quarters at the offices of the Plumbers' Company. The duty of the Board would be to examine plumbers both in theoretical and practical plumbing, and to grant to successful candidates a certificate and registration, which latter should qualify for the office of district examiner of sanitary plumbing work. If necessary, sub-committees should be established in large provincial towns to carry out the work in uniformity with the laws and regulations established by

the Metropolitan Board of Plumbers, or by Parliament. The committee should be made up of certificated plumbers.

Mr. E. Knight (Southwark) maintained that by the establishment of such boards, owners of houses would obtain certificates as to the proper sanitary condition of their dwellings. The advantage of this was manifest in connection with the letting and selling of houses, and it would at once strike at the root of defective sanitation. The Board of Examiners should, if possible, be invested with some local authority, and should at all events hold a well-defined and acknowledged position. They would work in connection with the parochial authorities, being careful at the same time not to usurp the duties of the inspector of nuisances. The charge for reports should be a small one. A board might be formed in the first instance from members of the Court of the Plumbers' Company, assisted perhaps by one or two professional gentlemen.

In the discussion which followed, Messrs. Moore, Underwood, and others took part. Mr. Vacher proposed :—

'That this Congress is of opinion that in the event of the establishment of Provincial Boards of Examiners of Plumbing work, such Boards (firstly) should be affiliated with a Metropolitan Board; (secondly) should consist chiefly of trained working plumbers; and (thirdly) should be in connection with the provincial schools of plumbing.'

Mr. A. B. Clarke seconded the resolution, which was carried. The fourth subject was,

'THE REGISTRATION OF JOURNEYMAN PLUMBERS.'

Mr. R. Smith (Bermondsey), who read a paper, was opposed to the proposed registration, as it would open up a field for many abuses, and ultimately do great harm to the trade. Any board of examiners would consist largely of members with theoretical qualifications, and such a class of judges would in time exclude the practical men. There were means in their midst for obtaining properly qualified plumbers, viz., the trade societies. There was a prejudice against these, but he would ask what were the Plumbers' company and the other guilds but trade societies? Plumbers were the only competent judges of plumbing, and the young man who joined a trade society had the benefit of the experience of the older workmen.

Mr. Smeaton advocated the granting of some such certificate as was given in America.

Mr. Houghton thought that if the masters were registered first it would have the effect of keeping line-drawers and others from undertaking plumbing work.

The Chairman remarked that the registration would be a mark of high honour, showing that the person registered was a competent craftsman.

Mr. Swales said that in Melbourne plumbers had to pass an examination.

On Oct. 21 the following resolution, in continuation of the previous day's business, was passed :—

'That, in the opinion of this Congress, the registration of master plumbers and journeymen plumbers is expedient.'

Mr. Webb read a paper on—

'THE SUITABILITY OF MATERIALS USED IN PLUMBING, AND PARTICULARLY THOSE MATERIALS RECENTLY INTRODUCED AS SUBSTITUTES FOR LEAD.'

There was, he said, no known substance to equal lead for wear. Properly laid, not condensed, well dropped, and with all the expansion possible, he contended it was the best. But they must adapt themselves to circumstances. In model dwelling-houses, with drying-grounds at the top, it would be entirely out of place to use anything else but asphalt or cement and coke breeze. Turning to another substitute—viz., zinc, although much improved in the laying, it had no superiority over lead, being a hard metal without expansion, and liable to crack from the action of the acid in the process of soldering. With regard to cisterns he gave the preference to galvanized iron ones. In lead cisterns, and especially in certain districts, the action of water affected the weakest point of the cistern—viz., the outside of the soldering, and when

is not frequently cleaned out small portions were liable to be imported into the system; as a substitute, would not stand the test; and in cleaning them out a slimy vegetable matter to the sides, and there was a liability to vibration. With respect to soil-pipes he gave it to lead, and asked whether it was possible to make a joint with iron lasting for any length of time. It would occur in the cement of the joint, and would exude. Turning to the question of good-looking pieces of porcelain had been used, but these were complicated in construction, and not a sanitary point of view. He still adhered to the closet adopted by Bramah, but very much for all private dwellings where supervision was very old servant, the pan-closet, had been used of late. Though long since condemned, it was in large extent in use, and would live as long as the temporary as a hard-wearing closet.

The session which followed, Mr. Smeaton said he considered the ordinary pan-closet the best thing in buildings.

Mr. F. Wells (Worcester) affirmed that no cistern should be left for three months without cleaning.

It was not opposed to iron soil-pipes if they were sound. Iron and lead pipes did not always differ; in a comparatively short time there was a difference in the joints, and the foul air would escape.

The Court thought that plumbers should be left to their discretion very much as to which was the best material to be used.

Mr. Wood believed there was a great opportunity to push lead as against zinc. For internal use, good strong lead was the best, fitted neatly

to the remarks that glazed earthenware was suitable in country districts.

Mr. F. Wells was of opinion that lead was the most suitable for soil or any other pipes, because good and the action of any amount of acids or rust did not believe glazed earthenware used in water-pipes would last more than twenty years. He was in favour of the lead piping of the ancient conduit and which was as good as on the day it was made. In the case of Glasgow the engineer would allow nothing but lead to be used for the except for the large mains. He believed that lead was the best material.

Mr. (Glasgow) read a paper on

THE ABILITY OF FIXING UPON A SYSTEM BY UNIFORMITY IN THE QUALITY OF MATERIALS PLUMBING MAY BE INSURED.

That the idea of enforcing uniformity in the work in plumbing was not new, as articles in the water supply of London and Glasgow bore an official stamp. No regulations, however, of forcing materials or soil-pipes. The practice in cast-iron rain-water pipes inside houses, was to do duty as soil and waste-water pipes, and prohibited. In many cases it was customary to use hot-water waste-pipes for baths and wash-basins, and soil-pipe for the closets. This was a bad practice, the soil-pipe to stink worse than with only passing through it. In addition to condemning this, he objected to the way in which their joints were made—viz., by merely plastering a little on the top of the joint. When the joints were made and run with lead or sulphur they should be made of red lead, and the joints made with hemp and lead and twisted round the spigot end of the pipe when in position the hemp should be rammed down the joint run full with red lead.

The session which followed, Mr. W. R. E. Coles said that a standard of the quality of materials should be upon, to be specified in the tender.

An extra paper by Mr. Poole, of Norwood, on the same subject having been read,

Mr. Tidmas proposed,—

‘That the Congress is of opinion that it is expedient that the system of sealing or marking lead and solder of standard weight and quality be revived by the Plumbers’ Company, and that the Plumbers’ Company should be requested to consider whether the materials used in plumbers’ work as substitutes for lead are suitable, and whether standards of quality for such materials could be advantageously fixed on and verified by a recognised mark.’

Mr. Smeaton seconded the resolution, which was carried.

Mr. F. Wells (Worcester) opened the question of—

‘THE FORMATION OF DISTRICT ASSOCIATIONS OF PLUMBERS TO INVESTIGATE AND SECURE, AS FAR AS PRACTICABLE, CORRECTION OF EVILS AND ABUSES ARISING IN CONNECTION WITH THE TRADE.’

He said that if the formation of such associations would correct the evils of insanitary plumbing it would be a strong argument in their favour, and would effect a lasting good. Insanitary plumbing was the cause of a great amount of illness and death, and yet this sort of work was not only accepted, but sought after on the plea of cheapness. If district associations could be formed to correct these abuses, and carried on effectively, they would in the first place be the means of securing wholesome dwellings, and would give the honest tradesman his legitimate place in his trade.

Mr. Emptage (Margate) read a paper in which he said though much had been done through the labours of sanitarians and sanitary societies, it was small in comparison with what would be accomplished. Our American cousins had grappled ingeniously with the evils, and by the aid of a stringent plumbing law had almost regenerated the trade. In some places the law was carried out with great rigour, and he found that a plumber in New York was fined fifty dollars for putting in a dummy vent-pipe to a trap in the basement of a house; a master plumber was fined 150 dollars for allowing two dummy vent-pipes to be fixed; while another was fined 250 dollars for bad plumbing work in new buildings. An unregistered plumber lost the day in an action against a builder to recover his account for work done, because he was not registered, and was therefore working contrary to law. On the other hand, the permissive nature of our laws in regard to sanitary matters too frequently resulted in the presence upon our local boards of unscrupulous builders, and interested parties who used their position to silence the surveyor. The American law had been in force for more than three years, and seemed to work well. It protected the plumber to a great extent from dangerous competition, and enabled him to do honest work. There would be considerable difficulty in getting such a stringent law passed in England, but they might, with a good chance of ultimate success, aim at obtaining Parliamentary powers whereby all plumbing work in connection with sanitation would be carried out under the strict supervision of properly appointed and duly qualified persons, upon certain fixed and sound sanitary principles.

Mr. John Bailey thought it would be better to form associations to remodel their craft, than to allow it to dwindle into mere tinkership. He would call attention to the fact that the general public when they had cause of complaint against the trade were not aware that the plumbers did not design their own work, but were in reality carrying out other people’s ideas of sanitation. It was his opinion, after forty-five years’ experience, that it was necessary to form metropolitan and provincial associations, not simply for themselves, but for the registration of journeymen plumbers.

Mr. T. H. Court, in a paper, referred to the necessity which existed for an investigation of plumbers’ work. Architects in some instances, and the medical profession,

were now giving more time and attention to the laws of sanitary science than at any previous period. He was sorry to say he had been compelled to condemn a large portion of the work he had seen in different parts of the country. They would all agree that there was the greatest necessity existing for a thorough investigation of plumbers' work, for the correction of evils and abuses. This should be done by associations formed for the purpose. It would tend to raise a trade which was second to none in importance, for upon the plumber's work more than upon that of any other trade did the health of the nation depend. The associations should be composed of plumbers, as the work to be inspected would be plumbers' work.

Mr. Allan (Eastbourne) proposed :—

'That the resolutions and conclusions set forth in the preceding paper be referred to the Plumbers' Guild, with a request that they will confer thereon, with a view to take such action as may seem best.'

Mr. J. Murrell (Norwich), seconded the resolution, which was agreed to.

The Chairman, in summing up the work of the Congress, expressed the hope that it would result in the formation of a representative committee to carry out the recommendations and suggestions that had been made. He congratulated those who had attended the sittings on the practical character of the discussions, and the genial manner in which they had been carried on, and thought it would only be the beginning of what would be an ultimate and general success.

A cordial vote of thanks to the Chairman and to the Plumbers' Company closed the proceedings.

THE DUTY OF THE CHURCH WITH REGARD TO THE OVERCROWDED DWELLINGS OF THE POOR IN TOWNS AND IN THE COUNTRY.

This question was discussed at the recent Church Congress at Carlisle, when the Bishop of Bedford read the first paper, in which he spoke at some length of the past action of the clergy in their several parishes, instancing the work of such men as Mr. Quekett, Mr. Denton, Canon Girdlestone, Mr. Lowder, Mr. Billing, and Mr. Barnett. He also adduced the indirect influence of the clergy in promoting better habits among the people through education, they having been the pioneers in the work of national education. In answering the question—'What can the Church do to remedy the present evils?' the Bishop gave six answers:—(1) By creating, directing, and keeping alive public opinion; (2) by enlisting and encouraging workers in the cause, such, especially, as the band of ladies working under the training and direction of Miss Octavia Hill; (3) by stirring up the owners of property to a higher conception of their responsibilities; (4) by teaching the people in all ways to care for better homes and purer surroundings; (5) by infusing among the people a spirit of self-help and enlisting them in the work of self-improvement and improvement of their homes and habits; (6) by fostering the great movements for the promotion of temperance and purity.

Major Rankin, M.P., said that it was the duty of the Church to endeavour to improve the dwellings of the poor and to lessen the evil of overcrowding in every possible and legitimate way. The Church could work by private effort, both individual and combined. The clergy might be most useful in the cause of stimulating every effort at self-help in the way of cottage building societies or Starr-Bowkett societies. It was a legitimate and rightful use of the pulpit for any clergyman to give his parishioners sound and useful advice therefrom on this question. Much had been done by individuals and companies to rebuild and improve insanitary dwellings and to offer them to the working classes at low though remunerative rents. In this kind of work it was within the power of nearly every one to do something. It was the duty of the Church to

stimulate efforts of this kind, as if bad property were to pass into the hands of kind and Christian owners, one great part of this difficult problem would be solved. It would be a work worthy of the Church to establish dwellings to meet the wants of the very poor by having one or two room tenements; and the establishment of cheap club or table d'hôte dinners in connection with such dwellings would be worthy of benevolent people. As to legal remedies, the Church ought to urge the constituted authorities to take action when required, for if that were done an immense step towards the rooting out of overcrowded areas would have been taken. The country was over-populated, and the only effective remedy was to cut off the supply of persons who now annually immigrate into our large towns from the country. The Church and the clergy could do a great and beneficent work by endeavouring to direct the stream of emigration from the country districts to our colonies rather than to our towns. We might establish industrial schools for the reception of poor children, either orphans or the children of vicious parents, with the object of training them for colonial life, and then sending them out to homes in the colonies.

The Rev. James M. Wilson, M.A., head master of Clifton College, said he advocated these principles:—That it is the duty of the Church (1) to influence opinion by collecting facts about the dwellings of the poor; (2) to urge its members vigorously to promote improvements in the material conditions of life among the poor; (3) to set an example by the expenditure of capital in ways not directly remunerative on the improvement, where desirable, of dwellings on Church property. He made the following recommendations:—That in the country sanitary associations be formed in each rural deanery to call attention to this and cognate subjects, and to collect and diffuse information as to facts and causes and legal remedies; that in each large town a committee—not limited to professed members of the Church of England—be invited by the bishop to assist him in an inquiry into the conditions of life of the very poor. A valuable precedent for this may be found in the city of Bristol. That a searching examination be made by the bishop in each diocese, or by some commission appointed by him, as to the condition and occupation of houses on the glebes and Church property in general. Some precedent for this may be found in the diocese of Lichfield. That the Houses of Convocation in both provinces be requested to collect and summarise for publication evidence on overcrowded dwellings and their effects on the moral condition of their inhabitants. The valuable report on intemperance will occur to all as a precedent. That the trustees of Queen Anne's Bounty be requested to advance money not only under the Dilapidation Act for necessary repairs; but, under proper conditions, on the report of some special commissioner appointed by the bishop for the purpose of improving cottages upon the glebe. 'Overcrowded dwellings (it is said) like all other unfavourable conditions of life among the very poor, are the result of the laws of economical science; but the very *raison d'être* and genius of Christianity is, by the implanting in men of a new motive and spirit, to fight such economic and social laws as act against the highest interests of society.'

Mr. William Inglis, of Leeds, President of the Church of England Working Men's Society, said respectable Christianity comfortably located in 'ceiled houses' could not dream of the fever dens, nurseries for disease, and centres of disaffection and discontent that almost touch it—the hideousness of the blind alleys and sunless nooks where the virtuous poor, the vicious poor, and the criminal classes are huddled together. In Leeds it was no uncommon thing to find five, six, and even more persons, many of them adults, and not always members of the same family, occupying one sleeping apartment. Many of these miserable and inadequate houses were those scandals of civilisation—cellar dwellings. The same condition of things was to be found in the slums of every town. We

reached the climax in London, where 30,000 men, women, and children have not even the shelter of an overcrowded home, but sleep in casual wards, common lodging-houses, or hide away in any hole like beasts; and where 60,000 families, of from two to ten persons in a family, each lived in one room. The effects of this crowding were (1) the ruin of young men and women, who drifted into the public-houses, the music-halls, and the street; (2) the absence of home training, most of the children being brought up in the streets that surround the slums, well named the 'Devil's Kindergarten'; (3) the infant mortality, which in Southwark district amounts to 305 per 1,000; and (4) a vast amount of physical weakness and deformity. Looking for the cause he found it partly in the pulling down of the dwellings of the poor for street improvements. Why should we not have Societies for the Protection of the Poor? It was the duty of the Church to set such machinery in motion and invite the co-operation of Christians of all denominations.

The Rev. C. W. Stubbs contributed a paper, in which he described the deficiencies of cottages in villages in Bucks, which were in a miserable and ruinous condition. In one village none were in a sanitary condition, and many had but one bedroom. Capacity, water-supply, drainage, and surroundings all condemned the cottages as unfit for habitation, and such cottages were to be found in many villages. Better cottages could not be provided because labourers could not pay their rents, but allotments of land would enable cottagers to do so. We could not wait for the operation of the law of supply and demand, nor for the elevation of the individual standard of comfort; but permissive legislation must be made compulsory, and sanitary conditions must be enforced by the appointment of inspectors and of medical officers of health. The Artisans' Dwellings Act should be extended to the counties.

The Rev. G. P. Head, of Hatfield, Doncaster, said the landlords had not yet recognised the duty of providing cottages for those employed in tilling their land. In his district few cottages had more than one bedroom, and clergymen who moved in the matter were threatened with the stoppage of charitable subscriptions. They wanted in such districts the support of public opinion. There were noble examples to the contrary. All that was required was that those examples should be imitated. In the Isle of Axholme many cottages had far less than the minimum of cubic space for each sleeper, but these separate properties were preserved for the sake of the votes they gave. Employers of labour in towns and cities should do something to house those who made their fortunes.

The Rev. A. E. Humphreys, of St. Matthew's, Cambridge, said he had endeavoured to form companies to repair cottages and build cottages, and experiment had shown that the work could be done and leave a profit of 4 per cent. A popular book containing the experience gained in different parts of the city would stimulate effort in this direction. The work should be brought before the undergraduates at the universities.

The President referred to inquiries that were being made in Bristol and Hull which were likely to lead to beneficial results, and which should encourage the clergy and the laity to take the work in hand. The question would be forced upon us by the progress of compulsory education, which was impossible under the conditions that had been described. You could not improve houses unless you could get at the hearts and consciences of the people who lived in them, as was being done by Miss Octavia Hill and others.

FIRST ANNUAL REPORT OF THE ASSOCIATION OF PUBLIC SANITARY INSPECTORS.

THIS association owes its existence in a great measure to the efforts of the able honorary secretary, Mr. Legg, of Hackney, and Mr. Lukes, of Gravesend, who first promulgated the idea of the association by letters sent to and inserted in the *SANITARY RECORD* of April 15, May 15,

July 15, 1883. These letters came under the notice of the Sanitary Institute of Great Britain through their secretary, Mr. E. White Wallis, who very kindly took the matter up, and advised and assisted in the matter of the arrangements for the preliminary meeting, which, owing to the courtesy of the members of the Sanitary Institute, was held in the rooms of that society at No. 9 Conduit Street, on June 9, 1883 (*see SANITARY RECORD* for June 15, 1883). In answer to some 150 circulars sent to inspectors in London and neighbourhood, about twenty members attended the meeting, which was presided over by E. C. Robins, Esq., F.S.A., a gentleman eminent in sanitary science, and who has always sympathised with and shown himself fully acquainted with the 'disabilities of inspectors of nuisances.' (*See SANITARY RECORD*, for Oct. 15, 1883, p. 176.) It was unanimously resolved that it was expedient that an association should be formed under the title of 'The Association of Public Sanitary Inspectors,' to which any inspector holding public office was entitled to become a member. It was also after some discussion resolved that anyone interested in sanitary science would be eligible to become an associate. A Provisional Committee of twelve of the inspectors present was formed to draw up a code of rules, and to make the necessary arrangements for starting the association.

The Committee met several times, and the first meeting was held on July 28, 1883, at the Holborn Town Hall (*see SANITARY RECORD*, Aug. 15, 1883). In answer to about 400 circulars, some forty inspectors met and adopted, with few alterations, the rules suggested by the Provisional Committee. The Executive or Council was elected from those present, and included the whole of the members of the Provisional Committee.

The following gentlemen have been nominated from time to time, and have consented to become honorary members:—J. Bristowe, M.D., LL.D., F.R.S., Dr. Bianchi, Professor W. H. Corfield, M.A., Edwin Chadwick, C.B., President, Dr. W. Collingridge, M.A., Brudenell R. Carter, F.R.C.S., T. Orme Dudfield, M.D., William Eassie, C.E., Capt. Douglas Galton, C.B., F.R.S., George Godwin, F.S.A., F.R.S., Baldwin Latham, M.Inst.C.E., James Lemon, M.Inst.C.E., Sir Robert Rawlinson, C.B., Dr. B. W. Richardson, F.R.S., E. C. Robins, F.S.A., J. W. Tripe, M.D., Lewis Angel, M.Inst.C.E., Dr. F. M. Corner, Dr. W. Johnson Smith.

At a later meeting the name of the present honoured president was proposed, and, in answer to the request of the Council, Mr. Edwin Chadwick, C.B., 'the father of sanitary science,' consented to become the first president of the association.

The Council have arranged to hold the meetings in future at the rooms of the Social Science Association, No. 1 Adam Street, Adelphi, Strand, London.

Monthly meetings have been held as follows:—On October 3, at the Holborn Town Hall, when Mr. G. B. Jerram (the chairman) gave his inaugural address. (*See SANITARY RECORD* for November 15, 1883, p. 269.) On November 3, at the Parkes Museum, a paper was read by S. P. Skipworth, surveyor and inspector of the Caistor Union, on 'The Position of the Sanitary Inspector.' On December 1, at 1 Adam Street, Adelphi, a paper was read by Mr. May, sanitary inspector of Ramsgate, on 'Tenure of Office.' (*See SANITARY RECORD* for December 15, 1883, p. 298.) On January 5, by Mr. T. Buckworth, of St. Saviour's, on 'Housing and Sanitary Inspection of the Dwellings of the Poor.' On February 2, by Mr. F. T. Poulson, of Tottenham, on 'Procedure in Relation to the Abatement of Nuisances.' On March 1, the whole evening was occupied in discussing the many important matters which arose out of those two papers. On April 3, a paper of some considerable length was read by Mr. Thomas Rees, of Guildford Union, on 'The Public Health Act, 1875, from a Rural Inspector's Point of View.'

The whole of the meetings have been well attended,

many inspectors showing their interest by coming long distances in order to attend them. It will be seen that the first two papers and the address of the chairman specially referred to the difficulties and disabilities of the sanitary inspectors; and such was the feeling evinced that something should be done to protect inspectors in carrying out their duties efficiently and fearlessly that it culminated in the following resolutions being unanimously adopted with a view to a memorial being presented to the Government, so that in any alteration which might be made in the sanitary laws provision might be made to strengthen the position of the sanitary inspectors, and provide the same means for superannuation as is provided for officers under the Poor Law administration. Resolutions.—1. That the position of the metropolitan, urban, and rural inspectors be assimilated. 2. That in order that the position of the sanitary inspectors may be strengthened, it is expedient that the appointment of all officers should be approved of by the Government Sanitary Authority, and no officer dismissed by any local authority without final appeal to, and approval of, the said Government Sanitary Authority. It was also resolved to send circulars to all the inspectors in the country, and some 1,944 circulars were sent out, resulting in about 550 being returned agreeing with the intentions of the resolutions, and showing that the association was thoroughly appreciated and supported by the inspectors throughout the United Kingdom. The president has seen the Home Secretary, the Right Hon. Sir W. Harcourt, and arrangements were being made for him to receive a deputation and memorial on the subject; but owing to the earlier adjournment of the Parliament, no opportunity has yet been given for the memorial to be presented. It is, however, hoped that early in the coming session the wishes of the members, and others supporting their action, will be brought before the Government, so that this important matter may be placed on a satisfactory footing.

The important question of the Housing of the Poor, which has excited so much interest in the minds of the public, has also received the attention of the members, and gave rise to a very interesting and important discussion, and the association has been represented before the Royal Commission for the Housing of the Poor by their president and chairman.

The other subjects dealt with in the papers concerned matters of much interest and importance, and the able way in which they have been dealt with by the authors of the several papers, and discussed by the members, fully shows that they are thoroughly alive to the advantages of the meetings and objects of the association.

The winter session was closed with the first annual dinner, which was held at the Holborn Restaurant on June 9, and was honoured by the presence of the president, Edwin Chadwick, C.B., who presided, Earl Fortescue, Baron De Liebhaf, representing the municipality of Paris, Sir Richard Owen, K.C.B., Captain Douglas Galton, C.B., Dr. Richardson, Dr. Carpenter, E. C. Robins, F.S.A., and James Lemon, M.Inst.C.E.

The list of members now comprises thirty-nine metropolitan, sixty-five urban, and forty-one rural inspectors, and three associates, in addition to twenty honorary members. It is hoped that many more inspectors will join the association, as it must be a considerable help to each inspector to have the advantage which such an association presents.

Since the winter session the members have met twice; the first time on July 12, when, through the kindness of Messrs. Doulton, the members present were shown over their beautiful works, and thence, by the liberality of Mr. Johnson, were conducted down the river to view the new process of dealing with offal and refuse at his works at Belvedere, afterwards being entertained at dinner by him at Greenwich. On the next occasion the meeting was held on August 9, at the Health Exhibition, when Professor Corfield met the members, and explained the defects of the unsanitary houses and the benefits of sanitary houses. Several exhibitors were present to explain matters of

interest in the Exhibition, which must have been means of imparting much valuable information to inspectors attending. It is worthy of record that association is the first scientific body that used Exhibition collectively for purposes of edification information useful to them in their daily work.

On Monday, August 11, the president, Edwin (wick, Esq., C.B., gave a most important and val address to the members on 'The Means to Pi Cholera.'

Some idea of the increase of the work of the as tion may be formed when it is stated that since the mencement 1,116 letters have been sent out, and circulars, and also 1,121 letters have been received being entirely independent of rules, pamphlets papers sent out or received.

The Council have pleasure in stating that the arranging for District Committees to be held in the and in the west; and it is hoped that as it is imp for country members to attend many of the meeti Londn, that the arrangement of these District mittees will enable the members in those districts to together and read papers and discuss the various s brought under their notice. The Council, in pre the results of the work of the year, cannot but cor late the members on the decided success which b lowed their effort in promoting the work of the assoc both in the number who have joined, and the presti status of the society. But they would urge the m not to be satisfied with the present position, but tr each individual will, in some way or other, either l tributing a paper on some matter of common inte by introducing new members, or attending the m help the association to still further progress, so may occupy that position amongst other kindred tions which such a one as this should, and must a by urging neighbouring inspectors, not already n of this association, to join it.

ILLUSTRATED SANITARY PATE

ENGLISH.

5,270. (1883.) VENTILATION. T. BAUCHOI N.B. [6d.]—This invention relates to a ventila plicable for the ventilation of halls, churches, d houses, stables, and buildings generally. The a the ventilator is as follows, the course of the cu vitiated air passing out therethrough being repres

the arrows shown in the sketch. The ascending cu of vitiated air passing off from the building strikes ag

form the oxide necessitates its replenishment possibly every five years, or perhaps oftener when the traps are used in a hot climate. It is essential, therefore, that the traps be constructed in such a manner that the mercury chamber may be easily, and at the same time quickly removed or reached without uncoupling the trap from its connections.

5,786. (1883.) PRODUCING FLUID CURRENTS AVAILABLE FOR VENTILATION. A. LORRAIN, Richmond, Surrey. [6d.]—This invention relates to apparatus for producing fluid currents, such apparatus, when acting on the air, being available for ventilation or blast, or by the reaction of the current produced, for propulsion of the vessel carrying the apparatus. The apparatus may also be applied to produce a current of water or other liquid,

so as to cause a stream thereof, or to effect propulsion by the reaction of the current produced. Fig. 1 is a front view and fig. 2 a side view illustrating one form of the apparatus. A is a sail or web of fabric or other flexible material which may be rectangular as shown, or might be of triangular or trapezoidal shape. One end of the sail A is passed round or linked to a stationary bar B, so that it can freely revolve round the bar. The other end of the sail A is in like manner connected to the crank pin C projecting from the crank arm D, the crank radius being somewhat greater than the distance of the bar B from the centre of the crank-shaft E. On causing the crank to revolve, the sail is made to sweep round with it, expanding to its full length when the crank-pin C is farthest from the bar B, and bellying as the crank-pin approaches, passes under and recedes from the bar B, as indicated by the dotted lines in fig. 2.

523. (1884.) IMPROVEMENTS IN VENTILATORS. R. POLLOCK & T. H. HERBERTSON, Engineers, London. [4d.]—The object of this invention is to obtain a more efficient ventilation by means of ventilators without mechanical motion, so constructed that rain-water cannot be driven into the extraction shaft, and consists in forming the ventilator with a series of deflectors arranged vertically, one series of deflectors being placed immediately opposite

the openings of the next series. By this arrangement the wind does not directly act on the extraction shaft, so that in whatever way the wind is blowing down draught in the tube will be prevented by the deflectors. In the annexed sketch fig. 2 is a sectional plan of fig. 1, through the line x y. The ventilators may be manufactured of galvanised

sheet-iron, zinc, or other metal, and may be made of convenient shape. Fig. 1 shows ventilator of circular form, consisting of four vertical deflectors in a circle. More deflectors may be used should the shape of the ventilator require it. The outer circle A represents the of the ventilator to which the vertical deflectors B are fixed, the series C being fitted opposite the opening the series B, and being strengthened at the outer edge stripes of metal C'; the tops of the deflectors being attached to a plate D. E indicates the extracting shaft tube connecting the ventilator with interior of the building. The wind impinging on the deflectors in any direction passing through the openings E', by creating a vacuum in the extraction shaft E, extracts the air below, and consequently more effectually ventilates building.

7,148. (1884.) IMPROVED APPARATUS FOR INTERMITTENT FLUSHING FROM TANKS, &c. W. B. OLOMEW, Lambeth, Surrey. [4d.]—This invention improved apparatus for the intermittent delivery of from flushing tanks and for like uses. As the cistern fills, the water rises within the bell as rapid does on the outer side until the mouth of the vent

covered by the water, and then no more air is escape from the bell or from the pipe a passing within it, for this is sealed at its lower end by dipping the box or water receptacle. The water continues rise in the tank compresses the air confined within bell, and this goes on until a sufficient head is obtained ensure the effectual action of the apparatus, and the water contained in the U bend of the small descending pipe is insufficient to withstand the pressure; this water is then suddenly blown out of the bend, and the compressed air escapes. The air finds vent in this direction than beneath the lower end of the large descending pipe a, because the depth of water in the U bend is less than the immersion of the lower end of the pipe a in the water receptacle d into which it dips. As soon as the air escapes from within the bell the water which was above near to the upper end of the pipe a (the vent tube b been so adjusted that this may be the case) rises within bell and pours in considerable volume down the pipe A syphon-like action is at once set up, and the water the tank or cistern ascends within the bell and pours down the pipe a until the tank or cistern is nearly empty. Air then enters into the bell beneath its lower edge, also by the vent tube, and the action is arrested until tank or cistern has again filled. During the discharge small quantity of water enters and is retained within

c f, and when the action terminates this water to the U bend at the lower end of the pipe e, eed be, closes it, ready for another action, but its bend will be refilled from the lower end during ery of the contents of the tank or cistern by the ke action. The strainer at the top of the recep- tops back solid matters which might choke the the bottom and so render it inoperative.

AMERICAN.

6. WATER-CLOSET CISTERN. WILLIAM SCOTT, Mass., N. Y. Filed Dec. 20, 1882.

—1. In a water-closet cistern, the combination, usual weighted lever and discharging-valve, of a

aft and nut, the combination being such, as l, that when the said lever ascends at its un- end it will operate against said nut, so as to t the discharge-valve through the medium of said aft, and also such that said screw-shaft will then in and descend through the said nut until the -valve shall be reseted.

12. SEWER INLET. EDWARD Z. COLLINGS, N. J., and CHARLES F. PIKE, Philadelphia, Pa. g. 10, 1882.

ater from a source of constant supply is sprayed trap through removable screens which are above red to the inverted cup-shaped trap valve.

1.—1. The combination of inlet A, trap a, and erminating in a spraying device, c, and leading stant source of water supply, x. 2. The combina- nlet A, having trap a, the pipe c, the spraying i, and reservoir E, substantially as and for the pur- forth. 3. The inlet A, having groove a', inverted cup or valve a', having stem a', and screens or B B.

00. BOWL FOR WATER CLOSETS. JOSEPH J. B. New York, N. Y. Issued April 17, 1883.

1.—1. A bowl for water-closets, having a slop le to form an integral portion of it, and constucted shing rims or ducts, also forming integral portions ame combined structure, and arranged to flush or spective, both the top of the slop safe and the of the bowl.

275,803. SEWER FLUSHING DEVICE, EDWARD Z. COLLINGS, Camden, N. J., and CHARLES F. PIKE, Philadelphia, Pa. Issued April 17, 1883.

A disinfectant reservoir is located in the path of the pipe, which supplies a constant flow of water into the flushing device, and from there through a grating or nozzle into the sewer trap.

Claim.—1. The combination, with a sewer inlet provided with a flushing device, of a pipe or conduit leading to a constant source of water supply, and a reservoir, adapted to contain a disinfectant, located in the path of said pipe. 2. The combination, in a sewer inlet, of a flushing device, a water supply pipe E, and nozzle or grating B¹.

292,055. COMBINED TRAP AND OVERFLOW FOR WASH-BASINS, WATER-CLOSETS, SINKS, &c. CARROLL L. RIKER, Brooklyn. Filed July 18, 1883.

Claim.—1. The combination, substantially as hereinbefore described, with the basin, of the closed vessel situated beneath said basin, the pipe bent to form the trap,

and extending from the bottom of the basin into and near to the bottom of the closed vessel, the discharge-pipe extending from the top of the closed vessel, and turning downward, the connecting-pipe, which extends from the highest point of the trap into the discharge-pipe, and the stop-cock fitted into the connecting-pipe.

294,150. BATHING APPARATUS. JOHN RANSOM, Williamsport, Pa. Filed June 15, 1883.

Claim.—A portable cabinet for bathing purposes the bottom of which is composed of one or more shallow pans

adapted to retain water that may be splashed over from the bath tub or tuba.

A portable cabinet for bathing purposes, consisting essentially of bottom pans adapted to be nested together, a rear wall secured vertically to the rear edge of the rear pan, end walls secured vertically to the ends of the rear pan, a top secured to said rear and end walls, a hood depending from the front edge of the said top, and having triangular end pieces, end walls, and a front wall secured to the ends and front edge of the front pan, and connected detachably to the end walls of the rear pan and to the hood, and suitable means for ingress and egress, and for ventilation.

294,489. REMOVABLE BOTTLE-TRAP. GEORGE M. McCLOSKEY, Brooklyn, N.Y. Issued March 4, 1884.

Claim.—In a removable bottle-trap, the combination, with a cylindric cup having its mouth span into a neck which is provided with a female-screw tube, of the tubular male-screw, having an external circumferential flange, and coupling-ring to receive the inlet-pipe.

294,562. PIPE AND OTHER JOINTS. JAMES A. BALDWIN, Jun., East Jaffrey, N.H. Issued March 4, 1884.

Claim.—1. The packing-ring having a plain surface on one side, and an annular groove in its opposite side. 2. The packing consisting of the ring with a plain surface on one side, and an annular groove in its opposite side, the plain-surfaced side of said ring being inserted into a groove of one part of the joint, and the projecting grooved side of said ring bearing against the face of the opposite part of said joint.

286,951. STENCH-TRAP. RANDOLPH McBER, Washington, D. C. Filed May 24, 1883.

Claim.—A bell-trap comprising a cup, A, drain-pipe, C, and inverted cup or bell D, rigidly supported in place from above by the bridge-plate E, whereby the chamber around the bell and the edges of said bell are left clear and unobstructed, combined with a hinged grated cover which may be opened and closed independently of and without disturbing said bell.

294,758. DISINFECTOR. CHARLES A. CATLIN, Providence, R.I. Issued March 11, 1884.

Claim.—As a new article of manufacture, the disinfectors,

consisting of the solid deodorising-ball D, provided with length of cord or other suspending means secured to

ball, and adapted to be attached to the lid of a closet.

NEW INVENTIONS.

THE TORBAY PAINT COMPANY'S PATENT STAINS FOR WOOD.

IN the SANITARY RECORD of May 15 attention was called to the fine paints of this company, whose works are at Brixham, Devon, and their London offices at 27 Street, E.C. The company then drew the attention of the reporter to their stains for wood of a more simple and effective than those generally in use. Having made an experiment with this stain on a wood-flooring, exposing it to a great amount of wear, the writer is now enabled to give a reliable opinion of its merits, and can testify to its excellent qualities. Hitherto the great objection to stains for floors or any woodwork has been the number of operations necessary to obtain the proper result: thus staining, sizing twice, and afterwards varnishing, has been carried out to make a complete work; and when the varnish has been done the varnish often flakes off in patches, and a room in constant use the operation has to be performed again in a comparatively short time. The Torbay Company's stains obviate a great amount of trouble and nuisance, and a better and more lasting result is obtained. Presuming the flooring to be dry and one coat of the stain without any sizing effects the stain appears not only to incorporate its color with the wood and dry quickly, but leaves a beautiful appearance, bringing up the grain of the wood and concealing it, and producing a better imitation than the copies of real wood by graining. The stains are supplied in light and dark oak colours, mahogany, &c. For the up to the pristine appearance of the stain the firm have produced an admirable floor polish to be occasionally used by the housemaid in her daily duties. The advantage of this stain over painting are manifest; and as the stain is now fairly set in for square carpets, Indian rugs, &c. demand must naturally arise for such an efficient preparation. The sanitary advantages of stained floors over nail carpets are now thoroughly recognised, and therefore not be further insisted on. Messrs. Stevens & Co., proprietors of the Torbay Paint Company, will supply particulars of their invention if applied to at the given address.

AN APPARATUS FOR REGISTERING QUANTITY OF MILK SUPPLIED TO HOUSEHOLD.

A NOVEL invention for receiving and registering quantity of milk daily supplied to a family has been patented by a London dairyman, and is being manufactured by Messrs. Bodill, Parker, & Co., of Great Horse Row, Birmingham. In the absence of illustration impossible to point out the various features in detail, a fair idea of the apparatus may be formed from the following description. It consists of a framework on which is fixed on the inside of the door, and communicating with it on the outside is a dial-plate numbered from 1 to 12, with a hand for pointing, and below this are

a pipe, through which the milk is poured and placed inside to receive it. The inner out-plate has a movable plate that passes to and fro, and there is a certain amount of simple connected with it. Each figure on the dial marks, and dots between half-pints, and it is a dial is sufficient to indicate a week's supply. The dial to stand at *nil*, and the domestic being at it at fig. 1, representing a quart, she moves which is actuated by means of a spring, and can be moved in one direction to that figure, and places the stand formed to receive it. This stand is provided with a chain and balance weight, which acts upon the plate that moves over the dial. The weight of the jug depresses the stand, balance weight to rise, and the plate to move to open the spout, ready for the milkman to pour quantity registered on the dial. This operation prior to each delivery, and at the week's supply received is noted, and the dial reset for the next week. The advantages of the invention are absolute security against milk being tampered with after delivery by the milkman in early morning and to the milk vendor a great saving of cans, which probably has weighed materially with those who take their 'walks abroad' early with the small milk can at the doors of houses for the maternal supply, placed there by the fore the inmates are stirring, and if they utter a thought must be fully alive to the counteracted by the milk. This invention is a guard against them, and as a security to the can be safely recommended.

A NEW CURTAIN-HOOK.

DILL, PARKER, & Co., are also the patentees of a new curtain-hook, aptly named 'and Fly,' the hook we presume being the end of the curtain the 'fly,' the former holding securely that it cannot escape. The invention has soon caused a revolution in the manner of curtains to cornice-pole rings, and a similar appeared for that purpose, so that the old ring each hook required for the suspension of curtains is now practically obsolete. By the use of this device the inconveniences of the ordinary

curtains, if not carefully adjusted, are avoided. The 'Fly' hook cannot become unhooked from the curtain, or jerked out of its position when the curtains are being drawn. There is in the new invention a hook at all, but rather a spring loop, which, as soon as it has been passed through the curtain, cannot escape from it; when in use the whole of the curtain is thrown on the point of attachment, and the tendency to force open the pin and drag the curtain away is thus avoided. The hook is capable of bearing a strain of several pounds, and its construction is simple. The advantages of hanging curtains on this plan over others are distinctly obvious.

VENTILATION OF THE 'CASTALIA,' NEW SMALL-POX HOSPITAL SHIP.

THE Metropolitan Asylums Board, having acquired the twin-steamer *Castalia*, have converted it into a small-pox hospital. The arrangement of the pavilions on the upper deck is on rather a novel principle, being in 'echelon,' By this means the greatest amount of light is secured all

round the pavilions, besides furnishing free air-passages for the purposes of ventilation. Accommodation is provided for two hundred patients, being more than can be

accommodated in all the other small-pox hospitals in London put together. Taking a warning from the evil results accruing from the defective ventilation of most hospitals, the Board wisely determined to pay special attention to the ventilation of the *Castalia*, and to assist them in their endeavours they adopted the prudent course of calling in to their aid the highest authorities on the subject that could be secured, Professor de Chaumont, F.R.S., being the principal adviser. After careful consideration and inquiry, it was by the Board decided to adopt Messrs. Robert Boyle & Son's system of ventilation as being the best and most suitable for the purpose; and the Local Government Board having approved of it, and sanctioned its adoption, Messrs. Boyle received instructions to proceed with the work. This is one of the largest and most important ventilating contracts that the firm has yet undertaken; and from the peculiar nature of the application it is also considered to be one of the most unique examples of ventilation in this country, or indeed in the world. For the extraction of the vitiated air there are provided twenty of the self-acting air-pump ventilators, each six feet in diameter, connected with the wards (as shown on the accompanying diagram) by means of iron shafts, measuring from thirty inches to four feet diameter. There are also sixteen air-pump ventilators, three feet diameter, connected with the water-closets, lavatories, bath-rooms, &c., &c. Fresh air is admitted all round the wards by means of openings cut through the walls at the floor level. The air passes in through these openings and over hot-water pipes, which are encased in a false skirting made of iron perforated at the top, to permit of the air being equally and imperceptibly filtered in and diffused throughout the wards. The supply of air is regulated by valves or shutters, worked by means of screws. This arrangement is that of Mr. Adam Miller, engineer to the Board. Great interest was taken by scientific and medical men in the progress of the work, considerable curiosity being excited as to how it would answer. Accordingly on completion experiments were instituted by the Board to test the action and efficiency of the system. The results were of the most satisfactory nature; indeed, quite beyond anything that might have been reasonably expected by even the most sanguine. After an extended series of experiments to test the air-pump ventilators under all states of weather—when there was a good wind blowing, and when there was no wind at all—it was found that the ventilators were extracting at the rate of five million of cubic feet of air per hour, the air in the wards being entirely changed once in every five minutes, whilst there was not the slightest disagreeable draught experienced. During the whole of the tests not the slightest down-draught was found in the ventilators. There were several anemometers used placed in the shafts of the ventilators, readings being taken every two hours; anemometers were also fixed outside to register the velocity of the wind. Messrs. Boyle were not present at any of these tests except the first, they (the tests) being carried out by the engineers and others appointed by the Asylums Board.

Dr. Bridges, Her Majesty's Chief Inspector of Hospitals, after carefully testing the system, expressed his high approval of its action, informing Messrs. Boyle that even when he tested it in a calm he found a considerable up-draught in the shafts, and at no time any down-draught. Sir C. Dilke and other members of the Royal Commission on the Dwellings of the Poor, accompanied by a large and distinguished party of gentlemen, visited the *Castalia* for the purpose of examining its arrangements, and expressed themselves highly satisfied with all they saw. Messrs. Boyle applied their system to the *Castalia* under a guarantee, and it may be taken as good evidence that the Asylums Board was satisfied that all the stipulated requirements had been fulfilled and the system a success, when it is mentioned that their account was paid immediately after the conclusion of the experiments.

The system is also applied to the ambulance and transport steamers *Red Cross*, *Endymion*, and *Albert Victor*.

The value of these experiments to Messrs. Boyle must be very great, as they are really practical tests and prove the real worth of their system and what it is capable of doing. There is only one correct and really reliable way of proving the efficiency of any ventilating arrangement, and that is by the test of actual and extended practical experience. Lecture-room experiments, as all privately conducted experiments can only be called, may be all very well in theory and show certain results, but in actual practice the results are generally found to be very different, as in the case for instance of the *Kew* and other experiments which were supposed by their originators at the time to have entirely settled the question, which were found by no means to accord with the working results carried out on a large scale.

CORRESPONDENCE.

Andi alteram partem.

[All communications must bear the signature of the writer, not necessarily for publication.]

WATER-FILTERS.

At the bidding of the editorial notice in your October number, we reluctantly beg to express our views on the 'International Health Domestic Water-Filters.'

You will admit that the material employed in filters is a point of the greatest importance. Here we object to the use in the 'International' filters of animal charcoal, as it has been proved by all official evidence during the last ten years to *promote* the development of the low forms of organic life. We submit that all evidence we have on the subject points to the probability that the development of those organisms, which are the cause of typhoid, cholera, and similar diseases, will be equally *promoted* by the use of this material in filters.

If any one sends out a *bond fide* challenge, such as you refer to, his first duty is to state a clear case. The statement that 'a patented material, composed of several ingredients' is used in those filters besides charcoal, is clearly a complete bar to criticism such as you invite. That material may be superior to all others hitherto known, or it may be rubbish; no one can express an opinion on something that is unknown to him.

Amongst the points forming the 'challenge' to which you refer there is a remarkable absence of the most important point—viz., the chemical and physiological purification of the filtered water. If the promoters of the 'International Filter' consider this subservient to working, on which so much stress is laid, we repeat what we have before remarked that the easiest way is not to filter water at all.

As regards construction, the sections given in 'challenge' are not sufficiently intelligible. We subsequently took the trouble to send to headquarters in Adelaide Street, to ask for some illustrated papers. A remarkable reply was received that they are not yet printed! It is certainly remarkable that before their papers are printed the promoters of the filter know precisely that its purifying action will last for five years. This, as far as the durability of animal charcoal is concerned, has, as you are aware, been distinctly contradicted by all more recent official and private researches on the subject.

To return to the construction, the section given and that in the 'challenge' are essentially different. There is in the former no 'intervening perforated plate' nor any 'loose medium.' The 'important point' made of the filter being in one solid piece of earthenware is unintelligible to us, as we scarcely know of a single filter in which this is not the case. The statement that no artificial joints or connections have to be made in the filter is contradicted in the next sentence, in which it is stated that an earthenware plate is fixed and secured by cement.

one good point in the section in the 'challenge' is provided with two taps. Servants may use them, and should the 'filtered' tap ever pass water the other will always be handy. I scarcely think it prudent that in your 'secured' water-tap should be in the same position the unfiltered tap is in the other. Even 'poison' has not prevented fatal mistakes by it, as may readily happen, some one has a plan of the section side by side with another in the 'challenge,' is the inventor prepared to let servants will always use the right tap? objections are these:

1. Use of animal charcoal for the reasons stated.
2. Secrecy about the other filtering medium employed renders it impossible to accept the 'challenge' should somebody have nothing better to do.
3. Mission in the 'challenge' of any reference to an important point—viz., the criterion of the physiological purification effected by the

statement that the filter will remain efficient for more than the papers describing it have been wanted to know why this has not been extended

to two taps, one for 'filtered,' the other for unfiltered, which must the more lead to mistakes, as in the filter the unfiltered tap is in the same place as the 'filtered' tap in the other.

In deference to the value of your space we make off, adding only that we have failed to make a single point in favour of the filter.

Now done, as we hope for ever, with the 'Universal Filter,' which we are told has already been the 'Universal Filter,' we ask your indulgence for the exception to your remark that we (amongst others) consider it sufficient that our filters are under the patronage of the Health Exhibition. We do not by any means attach such weight to this. That test consisted of a simple analysis, and can neither add anything to all the official inquiries during the last ten years, nor detract from them. They, one and all, have pronounced the 'Spongy Iron Filter' to be the only water purifier that is secure. The same, as you well know, has been confirmed by practical experience, through our filters in several instances of the greatest

We remain, sir,

THE SPONGY IRON FILTER COMPANY.
10 Oxford Street, London, W.C.
Oct. 24, 1884.

I have kindly sent me a proof of a letter from the 'Spongy Iron Filter Company' that is to appear in your issue in which some reflections are cast upon the description of the 'International' Filter that appeared in your October issue, I think it not out of place to make a few remarks upon the letter for the purpose of putting myself right with your readers and the public before alluded to. With the 'challenge' I have to do; it is simply an advertisement that is inserted in other sanitary journals, and is laid down on an intelligible basis that, I hope, in the interests of the public at large, will be taken up; but the question of the filter is a different matter. Your objections to animal charcoal, and seems to me I did not state what the other filtering medium consisted of for reasons of my own. I did not say animal charcoal was good, but if the Spongy Iron Filter was ready to accept the challenge, the International Filter, in my will of course make known what their opinion is composed of, and I have no doubt that the letter of the Spongy Iron Filtering Company will lose no time in answering it, for if the filter is good or bad, they are, I believe, to challenge they have set forth. As to the description of the filter, I maintain that it

is correct; but, unfortunately, an error was made in inserting the illustrations. I understand, on inquiry, that the engravings were not sent to time, and came only when the journal had actually gone to press, and in the hurry they got reversed: viz., the one intended for the notice got placed in the advertisement, and *vice versa*. If the advertisement engraving be placed in the notice, the description of construction is correct. Your correspondent says I contradict myself, for after saying the filter is in one piece, I say, 'An earthenware plate is fixed,' &c. Quite so, but I maintain that this plate has nothing to do with the filter proper, the receptacle for unfiltered and filtered water, perforated plate, &c., being in one solid piece of earthenware; the plate 'cemented' in, to which they take exception, being the extreme bottom and having nothing whatever to do with the filter itself.

THE WRITER OF THE NOTICE OF THE
'INTERNATIONAL FILTER.'

AWARDS FOR VENTILATORS AT THE HEALTH EXHIBITION.

As we are informed that a select number of ventilators have been tested by the jury on ventilation at the late Health Exhibition, for the purpose of assisting them in adjudicating the awards, we beg to state that we knew nothing of these tests until they were completed, nor was our air-pump ventilator included amongst those tested. It appears that our ventilator was not the only one excluded, as several other exhibitors of ventilators were also not invited to submit their ventilators to the tests. Now it would be interesting to know why so many ventilators, ours amongst the number, were excluded from these tests, seeing that they were all sent to the Exhibition for the purpose of competing for prizes. We are afraid the jury have committed a blunder they will have some difficulty in explaining; for they may depend upon it that the matter will not be allowed to drop until it has been sifted to the bottom. We understand that the method of making the tests was a complete farce, the ventilators being placed inside a tube 8 feet long by 3 feet square, and a blast of air driven on to them by means of a fan; the bottoms of the pipes attached to the ventilators were also inside the tube. It is scarcely credible that such ignorance amongst professed scientific men could exist in this the nineteenth century.

We formally protest against the awards given for ventilators on the ground that our self-acting air-pump ventilator was not tested, and that we were not invited to submit it for the purpose of being tested along with the others, and that, therefore, the awards given do not show that the ventilators receiving them were justly entitled to them.

ROBERT BOYLE & SON.

64 Holborn Viaduct, November 4.

VENTILATION AND VENTILATORS.

The letter from Messrs. Sharp & Co. under the above heading, on page 189 of your October issue, is one of the best I have read for a long time upon the subject, and I should be glad to learn more as to what Mr. Low's scheme for relative testing is.

Testing on the U tube is very good. This is not a new idea, as it was done by Mr. S. S. Hellyer along with other plans, as explained in his work—'The Plumber and Sanitary Houses.' The tests should not be confined to that plan alone, as the double tube system with two anemometers (as done by Mr. Hellyer) is also a good plan. Another plan, which I think would be useful, would be to test the ventilators—either one, two, or more at a time—on separate pipes, and have a large metal or wooden box with two glass panes in it, and a deep self-closing valve, and mark which of the ventilators opened this valve best and kept it longest and widest open.

The ventilators tested should be freely exposed to the wind; or if artificial wind be produced, it should be of sufficient volume to be a good and fair imitation of the

wind, and such 'wind' should have sufficient scope to fairly envelope and freely pass all the ventilators. From want of attention to this, some intended relative testing I lately saw was quite useless in my opinion, so far as giving any real comparative results was concerned.

I quite agree with Messrs. Sharp & Co. in their condemnation of the use of movable cowls for exhaust purposes, as they often stick fast and stand the wrong way. Hence, for permanent use they are not to be commended; and I say so even although I patented in 1877 the Glycerine-jointed Veering Cowl. After a long series of experiments with them I have given them up entirely in favour of the *fixed* exhaust ventilators, and the question to decide is—Which of these is the best?

Mr. S. S. Hellyer in 1880, as the result of the elaborate experiments he had made, stated that Buchan's Induced Current Fixed Ventilator was the best; and as yet I have not seen any substantial evidence to controvert this.—I am, &c., W. P. BUCHAN.

21 Renfrew Street, Glasgow, November 5, 1884.

VENTILATION.

The remarks on pp. 189 and 190 by Mr. W. H. Drake are very interesting, and as the reader peruses them he wonders what the writer is driving at, until just at the close he suddenly discovers that all he has read is merely the prelude to a puff of a particular exhaust ventilator. In short, one is reminded of the farce of a long grace before dinner and a scarcity of meat.

The ventilator which Mr. Drake mentions is not 'really sealed from down-draught.' (There is no wind-acting ventilator in the market which of itself is really entirely free from down-draught; all are liable more or less to such, unless provision be otherwise made to prevent it. It is sheer quackery to state otherwise, and to boast of 'absolute perfection.') When lately tested, as mentioned in a contemporary, it allowed down-draught very badly. Moreover, although patented by the firm he names in 1881, the reversing cap, and almost the exact words descriptive of its use, will be found in a three years' earlier patent of another party. Hence, as it seems to me, it would have been better for Mr. Drake to have acquainted himself more fully with the history and working of this style of ventilator before he wrote as he has done. VERITAS,

THE WATER-TEST.

A short time ago, I was staying at a friend's house in London; not being satisfied with the drains, he applied the water-test among others; the drain was plugged under the area, and water ran into the drain from the back of the house. It was calculated that upwards of 200 gallons were poured in; when the plug was taken out, some three gallons only came away!

Some months since, in the same house, the drains having to be examined, it was found that two lengths of drain-pipe, did not (in one place) meet by a foot!

If, in the face of these facts, people will persist in occupying houses where the drains are buried in the ground many feet below a concrete ground flooring, and without applying this simplest of all tests, viz., the water-test, they will only have themselves to thank for any inconvenience to which they may be put.

November 7.

J. R. T.

THE MEDICAL INSPECTION OF SCHOOLS.

In a letter to the *Times* of October 21 Mr. Balmano Squire makes the admirable suggestion that at Board Schools there should be 'periodical inspection of the scholars at short intervals by some competent person, and the prompt elimination from the school of infected individuals.'

He goes on to say, 'The machinery for this is ready to hand in the various parochial surgeons, who would doubtless be ready to accept the special office at a special remuneration.'

May I suggest that this inspection should be step further, and that it should be the duty of the inspector, not only to examine the children per se but also in every case of sickness to visit the child and inform himself as to its sanitary state; as children absent on account of illness.

In this way removable insanitary conditions: bad drainage or impure water, would often be noticed of which should at once be given to the officer of health for the district.

Merely keeping infected children away from schools by the use of little use without further precaution; but less the children are ill enough to be sent to the school it is impossible to prevent their mixing with healthy children between school hours; but as, broadly speaking healthy children come from the least health following up the cases detected at school would valuable help towards discovering the sources of a district.

It would be of great advantage to the public parish doctors were always in direct communication with the medical officer of health; and if both were on the same Board, instead of the medical officer of health being under the Vestry Board, while the medical officer of the sick poor is under the Board of Guardians, the clashing in carrying out their respective duties, disputes as to who is responsible for the patient suffering from infectious disease, the either case being paid out of the rates—would be avoided.

As things now stand, the medical officer's attendance to the inspection of places where he has notice that some nuisance exists; but if no notice it may happen that infectious disease or some condition dangerous to health continues for a long time out his being aware of the fact, or being in a position to blame for this ignorance.

Parish doctors have probably greater facilities than other persons for learning which are the most dangerous parts of a town or district. If a rule were laid down they should notify to the medical officer not only of infectious illness, but also those which might be expected to proceed from insanitary surroundings, frequently be enabled to prevent a large amount of disease by making a thorough inspection on the first suspicion that something was wrong.

At present the medical officer of health and the parish doctor act entirely independently of each other where infectious disease has actually broken out. The intimate knowledge of the sanitary condition of the district which every parish doctor must acquire if the public health is concerned, completely wasted. Moreover, the parish doctor is usually a hard-worked man, with little time to spare for inquiries beyond the sphere of his own immediate duties; so that his duty being limited to prescribing for his patients, he will not feel inclined to search out the origin of the ailments from which they suffer.

Of course the special remuneration of which Mr. Squire speaks would have to be extended to additional work also; but, considering that near epidemic is traced to causes that might with full knowledge have been removed in time to have prevented it, there can be no doubt that more thorough inspection would, in the long run, be a great saving in expense as well as of pain and suffering. E.

October 1884.

A NEW PARK FOR BRIGHTON.—The Presto, situate to the north of Brighton, has been formally set apart as a public recreation ground. The park covers two acres of ground. It was bought by the Corporation in 1862 from Mr. Benett-Stanford, of Pyt House, who married the heiress to the property, for 50,000*l.* that time about 10,000*l.* has been spent in laying out the grounds, which are now of an ornamental and a healthy character.

SANITARY JOTTINGS.

SANITARY.

R. PAGET, the Medical Officer of Health for the Kendal Sanitary District, reported at the last meeting of the authority that the water at two new houses, which had been complained of, had been analysed, and found to be pure; and that a close examination revealed that it was used by two dead kittens in the service pipe.

At a recent meeting of the American Association for the advancement of science, Professor Atwater read a paper on the 'Chemistry of Fish.' Flounder is the least nutritive of fishes; while the salmon, when fat, is the most nutritive. Oysters have least nutritive matter among invertebrates; and northern oysters are more nutritive than those from the south. The flesh of fish contains less fat and more water than that of vertebrates. Digestive ferments act upon the flesh of fish in the same way as upon that of the vertebrates, about 98 per cent. of the albumoids being digested in both cases. As ordinarily used, fish gives from 5 to 20 per cent. of edible matter. At the Eastbourne Fine Art and Sanitary Exhibition, a 'Special' Certificate of Merit (highest award), was granted Mr. W. P. Buchan, of Glasgow, for his ventilating and sanitary exhibits.

WATER SUPPLY.

At Vange, near Pitsea, in Essex, Messrs. Legrand & Atcliff, of London, have just struck chalk at the depth of 4 feet from the surface. Considerable uncertainty existed as to the depth the tertiary formation extended to this part of Essex. No less than 395 feet of London clay had to be penetrated before meeting with the lower tertiary beds, which latter have thus proved to be 129 feet thick.

HOUSING OF THE WORKING CLASSES.

*'How best to help the slender store,
How mend the dwellings of the poor?'*

At the Newcastle Diocesan Conference on the 30th ult., under the presidency of the Bishop of Newcastle, a paper was read by Mr. W. S. Daglish, Tynemouth, on—

THE HOUSING OF THE POOR IN TOWNS.

He spoke as one of the promoters of the Newcastle-upon-Tyne Improved Industrial Dwellings Company. No one, he said, could better testify to the degradation due to overcrowding than the clergy by whom he was surrounded. He pointed out the various agencies which might be brought to bear upon the question—the carrying out of the Artisans' Dwellings Act by corporations or local authorities; the formation by private individuals of model industrial dwellings; the carrying out of the improvement of industrial houses on the systems of Miss Octavia Hill; the extension of the common lodging-house system; the erection of suburban dwellings for workmen with easy access to towns; and lastly, assisted emigration. The formation of model dwellings by private individuals was one of the best means of solving the question, and there was no doubt they could be worked at a profit. Land for this purpose was always expensive, owing to the situation of the dwellings; and the way to meet this would be for corporations to grant land on easy terms, and for the Government to lend money at a lower rate of interest and in longer periods for repayments. To prevent undue competition with private builders, the dividends of the model companies might be restricted. Speaking of common lodging houses, he said that those in Newcastle, considering the class of lodgers and the rate of payment, were reasonably clean and comfortable. Houses in towns were much more convenient for workmen than suburban dwellings. Emigration, he said, ought surely to be the last resource for housing the poor.

Mr. J. Price, manager of the Newcastle Industrial Dwellings, read a paper on the same subject, which will be found *in extenso* at p. 200.

Mr. Albert Grey, M.P., contributed a paper on 'The housing of the poor in the country,' which was read by Canon Creighton. He believed he was well within the mark when he said that between 1841 and the present time nineteen out of every twenty farm cottages in Northumberland had been entirely rebuilt, remodelled, and improved, and the county could compare with any part of the world in the housing of its people. Taking the farm cottages as a whole, it must be said, to the great credit of the landowners of Northumberland, that they were nearly everything that could be desired; and this statement was based on answers to queries addressed to over three hundred representative people in the county. This improvement was going steadily on. The cottages might be divided into cottages on farms, cottages in villages, and cottages near mines. Of farm cottages only few were bad, the large majority were good, and very many were excellent. It had long been his belief that if the parochial clergy would draw up each year a report on the condition of the people in their respective parishes, with special reference to the condition of their houses, important and beneficial results would ensue. Let that report be sent to the rural dean, and considered at the Rural-dean Conference, at which an abstract could be drawn up and forwarded to the Bishop. It would not only give a valuable historical record, but would do much to form a vigorous public opinion, on which they must chiefly rely. He was led to believe that cottages in villages were very bad, and the chief hope for reform lay in the vigorous use of the powers of the sanitary authority, the action of which depended on public opinion. In mining districts there had been great improvement, but still there were many dwellings such as those in Seghill, the only reform for which was demolition. For those cases it was not so much more power that was wanted as a greater determination to use the powers already possessed.

Sir Charles Trevelyan, Wallington, confirmed the view that there had been a great, striking, and progressive improvement in country cottage dwellings. The root of all improvement was to raise the social life of the people. He agreed in the suggestion for an annual report from the clergy.

The Rev. W. E. Houldey, Newcastle, said no real steps had been taken in Newcastle, at any rate, by the municipal authorities to provide for those poor people who had been unhoused by the town's improvements, and overcrowding was intensified by that which was intended to prevent it. Newcastle suffered very much from overcrowding, but was not worse than other large towns. There ought to be practical restrictions as to the number of persons to reside in one room; separate conveniences for each family in tenemented property; an inspecting official independent of the municipal authorities, many of whom were often largely interested persons; blocks of dwellings near works; and habits of temperance and thrift inculcated.

Presiding at a Diocesan Conference at Leicester lately, the Bishop of Peterborough alluded to the question of housing the poor, which he said was closely connected with social purity. How they were to remedy the evil of ill-housing of the poor was one part of the question. The subject (he was glad to say) had occupied the attention of the Legislature, and the State might usefully within certain limits help in the elucidation of the difficulty; but outside these limits State aid would be dangerous. He did not expect much amelioration of the state of the poor from the State's action. If in London the State provided dwellings for the labouring classes, more harm would be done to them than to the rich, because people would crowd to those parts where houses were good; and this fact, with inevitable increase of rates, would lead to lower wages and to a more grinding competition among labourers. It was more the work for the Church than the State. They should make the people discontented with the filth surrounding them, and lead them to improve their dwellings by their own power.

PARKS AND OPEN SPACES.

*The law condemns both man and woman
Who steals the goose from off the common;
But lets the greater felon loose,
Who steals the common from the goose.*

OPEN SPACES IN LONDON.—Mr. H. R. Williams has addressed a long letter to the *Times* pleading for the extension of open spaces in London, and especially for the preservation of the lovely Hampstead Woods, now threatened with destruction. It will not be necessary for us now to endorse Mr. Williams's powerful advocacy of more breathing-places for pent-up Londoners; but there may be convenience in our reproducing the valuable details as to area and the like which he gives as to each of the metropolitan parks now in existence. These particulars are summarised below, certain additional facts being added from a very useful table compiled by Capt. Thompson, Secretary of the Metropolitan Public Garden, Boulevard, and Playground Association:—

EAST AND NORTH LONDON.

Victoria Park (300 acres), purchased with moneys voted by Parliament (£103,000). Under control of Office of Works.

South Hackney Common (30 acres).

Finsbury Park (115 acres). Acquired by the Metropolitan Board of Works for £119,904.

London Fields (27 acres). Acquired by Metropolitan Board of Works and maintained by them.

Hackney Downs (50 acres). Acquired by Metropolitan Board of Works and maintained by them.

Hampstead Heath (240 acres). Under control of Metropolitan Board of Works.

Clapton Common (9½ acres).

Stoke Newington Common (5½ acres).

North Mill Field (29 acres), situated in the 'Marshes.'

South Mill Field (28 acres), situated in the 'Marshes.'

West Ham Park (80 acres). Sold to Corporation of London for 25,000*l.* by Mr. John Gurney, who contributed 10,000*l.* towards the cost.

Epping Forest (5,530 acres, including Wanstead Park). Under control of Corporation, who took up the cause of the commoners and stopped the illegal enclosure of the forest. The total cost of acquisition amounted to 257,000*l.*

WEST END.

St. James's Park (83 acres).

Green Park (71 acres).

Hyde Park (390 acres).

Kensington Gardens (310 acres).

Regent's Park (400 acres).

Wormwood Scrubbs (194 acres). Under control of Metropolitan Board of Works.

Ealing Common. Under control of Board of Conservators.

SOUTH-WEST DISTRICT.

Battersea Park (250 acres). Under control of Office of Works.

Clapham Common (220 acres). Under control of Metropolitan Board of Works.

Tooting Common (207 acres). Under control of Metropolitan Board of Works.

Barnes Common (100 acres). Under Board of Conservators.

Wandsworth Common (160 acres). Under Board of Conservators.

[The extra-metropolitan suburbs in this direction are the best off in the matter of open spaces. Although Mr. Williams does not mention it, the county of Surrey was once upon a time practically all common land. Near to London the following commons still remain: Putney Heath and Wimbledon Common, about 1,000 acres; Mitcham and Merton Commons; Kew Gardens (270 acres), Richmond Park (2,255 acres), and Bushey Park (1,100 acres), both of which are Royal parks; Esher, Cobham, Leatherhead, Epsom, and Wisley Commons.]

SOUTH-EASTERN DISTRICT.

Southwark Park (63 acres). Under control of Metropolitan Board of Works. Cost £118,080.

Kennington Park (25 acres). Under control of Office of Works.

Peckham Rye (64 acres). Under control of Metropolitan Board of Works.

Greenwich Park (174 acres). Under control of Office of Works.

Blackheath (267 acres). Under control of Office of Works.

[Besides Plumstead (110 acres), Hayes, and Chislehurst Commons and Bexley Heath, outside the metropolitan area.]

METROPOLITAN PUBLIC GARDEN, BOULEVARD, and PLAYGROUND ASSOCIATION.—At the last meeting, held at 83 Lancaster Gate, Nov. 4, there was a very large attendance of members. Amongst others present were the Lord Brabazon (chairman), Lord de Vesci, Rev. Harry Jones, Mr. Ernest Hart, and Mr. J. Bedford. The secretary reported much work as having been undertaken and accomplished during the past month. Several letters have been written to the press and public bodies, including protests against illegal building operations upon certain disused burial-grounds. Grants of money were voted for the laying-out as a public garden of the churchyard of St. Bartholomew, Bethnal Green, the opening of the ground surrounding Christ Church, Battersea, the formation of a gymnasium at Stepney, and the further improvement of Canonbury Square. Letters were ordered to be written to the proper authorities concerning a proposed cricket ground in Kensington Gardens, the utilisation of the main drainage embankment, and the planting of trees in Brompton Road. Mr. Bedford reported the opening to the public of the gardens of Blackfriars Bridge, which have been tastefully laid out by the Corporation; and the Rev. W. Dawson announced that the conversion of the disused burial-ground, Benjamin Street, E.C., into a public garden, was to be immediately proceeded with.

EXHIBITIONS.

PARIS EXHIBITION. 1885.

THE International Exhibition of Manufactures and Processes (*Exposition du Travail*) will be opened on July 2, closing on Nov. 23 next year. The Exhibition is under the patronage of the Minister of Commerce, the Minister of Public Instruction and Fine Arts, and the Minister of Public Works. It will be held at the Palais de l'Industrie, Champs Elysées, and is to include a Science Annex and a Fine Art Annex. The London offices are at 1, Castle Street, Brompton. Communications from British exhibitors should be addressed to Mr. Edmund Johnson, Commissaire Délégué.

VENTILATION OF PUBLIC BUILDINGS.—Messrs. Robert Boyle & Son., 64 Holborn Viaduct and Bothwell Street, Glasgow, have applied, and are at present applying their system of ventilation and self-acting air-pump ventilators to St. Mary Redcliffe, Bristol, under the direction of Mr. Arthur J. Blomfield, architect, Christ's Hospital; Blue Coat School (second application); Bank of England, Liverpool; Reform Club, Liverpool; Public Hospital, Liverpool; District Hospital, Somerset; Town Hall, Sandwich; Beckett Hospital, Barnsley; National Schools, Stratford-on-Avon; 'Laranstein,' near Arnhem, Holland; Shorncliffe Camp of the Royal Engineers; Lambeth Carlton Club, Brixton; Grand Pump Room, Bath; St. Owen's Parish Hall, Jersey; St. Lawrence Parish Hall, Jersey; Bishop Lightfoot's Institute, Bishop Auckland; Maidenhead Town Hall; Royal Infirmary Naval Schools, Greenwich; Town Hall and Police Court, Dudley; Jewish Working Men's Club, Whitechapel; Devonshire Hospital, Buxton; Bilston Town Hall; Malton Theatre; Llandudno New Board Schools; Post Office, Chesterfield; Union Workhouse, Chesterfield; Inland Revenue Offices, Lincoln; Devon and Exeter Hospital, Exeter; Stroud Union Workhouse; Council Chamber, Keighley; New Police Station, Wandsworth; Council House, Birmingham; Small-pox and Fever Hospital, Birmingham.

INTERNATIONAL HEALTH EXHIBITION, 1884.

ords to Exhibitors in this Exhibition will be published immediately, in a clear and classified form, available for ready reference, in the concluding number of the 'Exhibition Supplement' of THE SANITARY RECORD. This number will also contain an Index to the descriptions of the Exhibits published in the 'Exhibition Supplement.'

NOTICES OF MEETINGS.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1 Adam Street, Adelphi, London.

Meeting of the Society will be held on Friday, Nov. 21, at 8 p.m. A paper will be read on 'NOXIOUS TRADES,' by Alfred Squire.

PARKES MUSEUM,

74A Margaret Street, Regent Street.

P.M., a Lecture will be given by Dr. Alfred Carpenter on 'THEORY AND CO-OPERATION IN SANITARY WORK.'

SANITARY INSTITUTE OF GREAT BRITAIN.

Examination, held on November 6 and 7, twenty-seven candidates presented themselves—eight as local surveyors and nineteen as assistants. The Institute's certificate of competency to the duties of local surveyors was awarded to Burton R. John Edward Worth, and Gilbert Thomson; and to discharges of inspectors of nuisances to W. Daley, J. Brooks, Wm. J. Keal, Thomas Wheat, W. Fraser, John Loach, and F. S. Winsor, J. T. Simpson, Arthur H. Rollinson,

APPOINTMENTS UNDER THE PUBLIC HEALTH ACT.

MEDICAL OFFICERS OF HEALTH.

Henry Hyslop, M.B. Univ. Edin., L.R.C.P. Edin., S. Edin., has been appointed Medical Officer of Health Wallend Urban Sanitary District, at £50 for one year, James Aitchison, L.R.C.P. Edin., L.R.C.S. Edin. (his deceased).

Wm. B. C. M. Univ. Glasg., has been re-appointed Medical Officer of Health for the Rishton Urban Sanitary District, Lanc., at £20 for one year.

Frederick Charles, M.R.C.S. Eng., L.S.A. Lond., has been appointed Medical Officer of Health for the Okehampton Sanitary District, at £50 for one year.

Thomas Edgar, M.B. Univ. Lond., M.R.C.S. Eng., has been appointed Medical Officer of Health for the Stamford Sanitary District, at the rate of £20 per annum, to 25, 1885, *vice* Heward, deceased.

Matthew Owen, M.D. Univ. Aberd., M.R.C.S. Eng., has been appointed Medical Officer of Health for the Surbiton Sanitary District, at £50 for one year.

Isidore Gidley, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Medical Officer of Health for the Bodmin Sanitary District, at £20 for one year, from Sept. 29, 1884.

Philip William Gwilt, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Medical Officer of Health for the Bournemouth Sanitary District, at £125 for one year.

Edwin Elsworth, L.R.C.P. Edin., and L.M., M.R.C.S. L.S.A. Lond., has been re-appointed Medical Officer of Health for the Thornton Urban Sanitary District, at 25 guineas, year.

ASSISTANTS, CLERKS TO GUARDIANS, INSPECTORS OF NUISANCES, &c.

William Richard, the Surveyor to the Moss-side Local Board and Urban Sanitary Authority, who was experimentally appointed Inspector of Nuisances, also, upon the death of the late Mr. Richard, has been recommended by the General Purposes Committee, been permanently appointed to both offices, at £275 and £60 per annum.

Mr. John Jacob, F.C.S., has been appointed Public Health Officer for the Borough of Falmouth, at 1 guinea per quarter.

Mr. Thomas, has been elected a Member of the Horncastle Local Board and Urban Sanitary Authority, *vice* Nicholson.

Mr. Samuel, has been re-appointed Inspector of Nuisances for the Hardingstone Urban Sanitary District, at £26 per annum.

Mr. William Ibbs, has been appointed Surveyor to the Northampton and Urban Sanitary Authority of Northampton, at £100 per annum, *vice* Pidcock.

BRUN, Mr. J. S., has been appointed Surveyor to the Oldbury Local Board and Urban Sanitary Authority, at £100 per annum, *vice* Davis, appointed Consulting Surveyor.

COOKE, Mr. William, has been appointed Inspector of Nuisances for the Longton Urban Sanitary District, at £100 per annum, *vice* Clements, resigned from ill-health.

CROSS, Mr. Ambrose Wootton, has been appointed Surveyor and Water-works Manager to the Loughborough Local Board and Urban Sanitary Authority, at £200 per annum, *vice* Baker, whose appointment has expired.

DEACON, Mr. E. H., has been elected a Member of the Knighton Local Board and Urban Sanitary Authority, *vice* Green.

DENSTONE, Mr. Robert, has been appointed Treasurer to the Sedgfield Guardians and Rural Sanitary Authority, *vice* Simms, resigned.

DICKEN, Mr. John, has been appointed Inspector of Nuisances for the Matlock Urban Sanitary District, *vice* Wright, resigned.

FRAPPE, Mr. H. D., has been elected a Member of the Burgess Hill Local Board and Urban Sanitary Authority, *vice* Eurling, resigned on leaving the district.

GOODINSON, Mr. Charles, has been elected a Member of the Rawmarsh Local Board and Urban Sanitary Authority, *vice* Cooper, resigned.

GOODLAD, Mr. Emanuel, has been elected a Member of the Matlock Local Board and Urban Sanitary Authority, *vice* Boden, resigned.

GRIMSHAW, Mr. Richard, has been re-appointed Inspector of Nuisances for the Rishton Urban Sanitary District, at £50 for one year.

GROVER, Mr. Walter, Solicitor, has been appointed Clerk to the Hemel Hempstead Guardians and Rural Sanitary Authority, at £65 per annum as Clerk to the Guardians, and such further remuneration as Clerk to the Rural Sanitary Authority, and to the Assessment and School Attendance Committees, as may be voted annually, and fees as Returning Officer, *vice* Mr. Charles E. Grover (his father), deceased.

HYDE, Mr. Josiah, has been elected a Member of the Wednesfield Local Board and Urban Sanitary Authority, *vice* McConnell, resigned.

JENKINS, Mr. William, has been appointed Inspector of Nuisances for the Wells (Somerset) Urban Sanitary District, at £40 per annum, *vice* Brown, resigned.

JONES, Mr. Thomas Inman, has been appointed Inspector of Nuisances and Surveyor to the Bangor and Beaumaris Rural Sanitary Authority, at £130 and £20 per annum, *vice* Lloyd, resigned.

LAMBERT, Mr. C., has been elected a Member of the Lillington Local Board and Urban Sanitary Authority, *vice* Whitmore, resigned.

LOWER, Mr. Thomas Henry, has been elected a Member of the Newhaven Local Board and Urban Sanitary Authority, *vice* Blackman, resigned.

MALBON, Mr. Henry, has been appointed Rate Collector for Florence and Dresden to the Corporation and Urban Sanitary Authority of Longton, at £60 per annum, and a bonus of £10 if the loss does not exceed 7 per cent., or of £5 if the loss does not exceed 10 per cent.

MATHER, Mr. Samuel, has been re-appointed Inspector of Nuisances for the Surbiton Urban Sanitary District, at £50 for one year.

MELLONS, Mr. Samuel Weatherall, has been appointed Sanitary Inspector, Inspector of Nuisances, and Inspector under the Sale of Food and Drugs Act, for the Parish of St. Luke, Middlesex, at £120 per annum, rising to £150, *vice* Eads, resigned.

MELVILLE, Mr. Alexander Samuel Leslie, banker, has been appointed Treasurer to the Gainsborough Local Board and Urban Sanitary Authority, *vice* Tritton, resigned.

OLIVER, Mr. John, has been appointed Inspector of Nuisances for the Bodmin Urban Sanitary District, at £10 per annum for three years, from Sept. 29, 1884, *vice* Jenkins, whose appointment has expired.

PERKINS, The Rev. H. E., has been elected a Member of the Arlecdon and Frizington Local Board and Urban Sanitary Authority, *vice* Harris, deceased.

PITTARD, Mr. Robert White, has been appointed Clerk to the Brentford Guardians and Rural Sanitary Authority, at £200 per annum as Clerk to the Guardians, £60 per annum as Clerk to the Rural Sanitary Authority, £50 per annum as Clerk to the Assessment Committee, £40 per annum as Clerk to the School Attendance Committee, and fees as Returning Officer, *vice* Ruston, deceased.

PRESTON, Mr. Frank Sansome, Solicitor, has been appointed Clerk to the Hinckley Local Board and Urban Sanitary Authority, *vice* Moss.

RIPPON, Mr. William, has been re-appointed Surveyor, Inspector of Nuisances, and Collector to the Consett Local Board and Urban Sanitary Authority, at £130 per annum.

SHELTON, Mr. Charles, has been re-appointed Inspector of Nuisances for the Ripley Urban Sanitary District, at £20 for one year.

SIMPSON, Mr. John, jun., has been re-appointed Inspector of Nuisances for the Wirksworth Urban Sanitary District, Derbyshire, at £30 per annum.

STEWART, Mr. Alan, has been appointed Surveyor and Inspector of Nuisances to the Maldon Rural Sanitary Authority, at £200 per annum, *vice* Brady, resigned.

STRACHAN, Mr. George R., has been appointed Surveyor to the Parish of St. Luke, Chelsea, at £400 per annum, *vice* Stayton.

THOMAS, Mr. Charles, has been appointed Collector to the newly-formed Bexhill Local Board and Urban Sanitary Authority, at 3 per cent. commission.

TUNSTALL, Mr. W., has been elected a Member of the Ilkley Local Board and Urban Sanitary Authority, *vice* Dewhurst, retired.
UNDERHILL, Mr. T. F., has been elected a Member of the Tipton Local Board and Urban Sanitary Authority, *vice* Whitehouse, resigned.
WADSWORTH, Mr. John, has been re-appointed Inspector of Nuisances for the Wyland Urban Sanitary District, at £22 per annum, for three years.
WATERS, Mr. Charles Fintin, has been appointed Collector to the Town Council and Urban Sanitary Authority of Guildford, at 45s. per cent. commission, *vice* Copas.

LOCAL INTELLIGENCE.

The salary of Dr. William Sedgwick Saunders, the Medical Officer of Health for the City of London, has been increased from £900 to £1,100 per annum (in addition to £100 per annum as Public Analyst), as from Midsummer last.

The Farnham Local Board and Urban Sanitary Authority have voted one hundred guineas to Mr. R. Mason, the Clerk, for extra services in connection with Local Government Board inquiries, the action at law, &c. in reference to the drainage, and for other matters connected therewith.

Mr. Charles Lineker Betts, whose appointment as Collector of General District Rates to the Melton Mowbray Local Board and Urban Sanitary Authority, we reported in our last, has, unfortunately, been obliged to resign from ill health.

There were 137 applicants for the appointment of Surveyor to the Corporation and Urban Sanitary Authority of Northampton, at £200 per annum.

The Taunton Town Council and Urban Sanitary Authority have increased the salary of Mr. Jam. a Henry Smith, the Surveyor, from £225 to £250 per annum, upon condition of his giving his whole time to the duties.

The Local Government Board have, upon the application of the Urban Sanitary Authority of Exeter, declared the enactment contained in Sect. 90 of The Public Health Act, relating to the making of by-laws as to houses let in lodgings, to be in force within the district.

At a special meeting of the Towcester Parochial Sanitary Committee, held at the Town Hall, a proposal to constitute it a Local Government district was negatived, but a resolution was passed requesting the Rural Sanitary Authority to apply for urban powers under Sect. 276 in the contributory place of Towcester.

Mr. Francis Coates, the late Chairman of the Newport Pagnell Guardians and Rural Sanitary Authority, has been presented with a marble clock, modelled after the Colosseum at Rome, a purse containing one hundred guineas, and an illuminated list of subscribers in a gilt frame. The clock bears the following inscription:—Presented, with a purse of gold, to Mr. Francis Coates, by his brother guardians of the Newport Pagnell Union and other friends, in testimony of their appreciation of his valuable services, during his term of office, for more than thirty years, as representative of the parish of Chicheley, as Vice Chairman of the Board for seventeen years, and Chairman for eight years. Oct. 22, 1884.

There were upwards of 120 applicants for the office of Surveyor to the Great Grimsby Town Council and Urban Sanitary Authority, at £200 per annum.

The Bournemouth Improvement Commissioners and Urban Sanitary Authority have, upon the recommendation of a committee, increased the salary of the Surveyor to £350 per annum.

The Rugeley Local Board and Urban Sanitary Authority have increased the salary of Mr. John Henry Freer, the Medical Officer of Health, upon his application, acted by the gentle pressure of the Local Government Board, from £10 to £20 per annum.

The Hutton with Roby Local Board and Urban Sanitary Authority, Lancashire, upon re-appointing Dr. E. F. Hall as Medical Officer of Health, have increased the salary from £20 to £30 per annum.

The Chesterfield Rural Sanitary Authority on re-appointing Dr. Angus Mackintosh, Medical Officer of Health in April last, reduced his salary from £420 to £315 per annum, which the Local Government Board hesitated to confirm, and urged the authority to reconsider it, which they did, but after discussion passed a resolution 'that they saw no reason to alter their decision' (See SANITARY RECORD, June 16, p. 225). The matter remained in abeyance until the authority quite recently inquired of Dr. Mackintosh if he would consent to the reduction, and at the last meeting, a reply from him was received and read, to the effect that he had no alternative but to do so, whereupon the clerk was directed so to inform the Board above, and request them now to give their sanction.

The Amersham Guardians and Rural Sanitary Authority re-appointed Mr. Hasegood Medical Officer of Health for one year, as reported in p. 232, but at the last meeting they received a letter from the Local Government Board declining to sanction the appointment at present. In the meantime Mr. Hasegood is performing the duties, but as the appointment is not complete until confirmed, he is not legally entitled to the salary. If the Guardians pay it before the Local Government Board have confirmed the appointment they will be surcharged by the auditor. It is true that the Board might, and no doubt would, remit it, but this perpetual conflict is very unattractive and troublesome, and ought by some means to be avoided.

There were seventy-six applications for the appointment of Surveyor, Drainage Engineer, Inspector of Nuisances, and Collector to the Wantage Improvement Commissioners and Urban Sanitary Authority at £120 per annum, which were deferred for consideration at a special meeting to be convened for the purpose.

STONBRIDGE IMPROVEMENT COMMISSIONERS AND URBAN SANITARY AUTHORITY. At the annual election the following were Members for three years, viz: Messrs. W. Griffin, W. Pa. J. Cadwallader for the East Ward, Messrs. W. Jones, G. R. and H. Hicklin for the West Ward, Messrs. H. James, J. D. and C. H. Collis for the South Ward.

The Worthington Local Board and Urban Sanitary Authority upon the recommendation of the Local Government Board the salary of Mr. William L. Eaglesfield, as Inspector of Nuisances, from £50 to £100 per annum, his salary as Surveyor at £100.

NOTES AND QUERIES.

Having for some time back been in the receipt of Queries relating strictly to sanitary work, and which it would be easy to without having to refer our correspondent to competent professional advisers, we have opened a column in which to register such Queries and Replies thereto as can fairly be expected from us, and our subscribers and readers are invited to make such use of this column as they may to benefit themselves and the community. Both Queries and Replies will, however, be subjected, if unnecessarily long, to a strict cur-

132. WHAT IS A 'NEW STREET'?

May I ask through your columns for an answer to what at blush looks suspiciously like a sanitary conundrum, viz. does an 'old street' commence to be a 'new street' when it has sent in plans for a number of houses to be built along what narrow public highway, and we should like to be under the model by-laws if we can? S. A.

[It is not possible to give an answer to this as a flippancy question, but the matter was fully discussed in Robinson v. Local Board (L. R. 21, Ch. D. 621), in Portsmouth Corpn. v. Smith (13 L. J. Q. B. D. 186.—Ed.)]

133. PUBLIC OR PRIVATE DRAIN.

Who is responsible for a drain in the circumstances stated, authority or the owners? The house drains of two different meet in a drain constructed jointly by the owners for the taking their sewage into the public sewer which runs a few feet of the premises. (The course of the joint drain in question down the private lane of the owners.) F. B. H.

[Sections 4 and 13 of the Public Health Act supply the answer. A 'drain' is defined by Section 4 as a drain used for the disposal of one building only, or premises within the same curtilage (the buildings in question are not). The term 'sewer' includes sewers and drains except those covered by the previous definition. Every sewer is, by Section 13 of the Act, vested in and under the control of the local authority, unless, indeed, it could be shown the sewer in question was made for the purposes of 'private' section 1 of section 13.—Ed.]

134. SANITARY PROTECTION ASSOCIATION.

1. In what towns are established 'Sanitary Inspection or Protection Associations,' where houses are examined in all details of construction, and a fee is paid for the work?
2. What fee is charged for examining a house, and reporting condition, also for superintending the necessary works, houses rented at 50s., 60s., and 100s. per annum?

[A list of such associations appears in the SANITARY MEDICAL RECORDS DIARY for 1884 (pp. 126 and 127), with all available particulars concerning them. A considerable number appear to be now in successful working, and a few corrected to date, will be given in the forthcoming issue of the DIARY for 1885. The London Sanitary Protection Association whose address is 1 Adam Street, Adelphi, may be taken as of these institutions.]

[3. The charges are not uniform. The fee for examining a house, covered by the subscription payable by members.—Ed.]

135. A POINT OF SANITARY LAW.

You will oblige me by giving your opinion under 'Notes and Queries' as to the point of sanitary law raised in the case of 'The Rural Sanitary Authority v. J. Watson,' reported on page 215 of THE SANITARY RECORD for September 25. Also as to the legality of magistrates who are also members of the poor authority.

[We do not see that a second notice was required. It, however, depend on the form of the summons. The offence should have been framed under Section 45 of the Public Health Act, viz. 'making default in complying with the requisition previous notice.' If this was the charge, no further notice necessary, but if the charge was for something else, the magistrates may have been right. Section 258 of the Public Health Act empowers justices who are members of a local authority in cases in which such authority is concerned. If, however, they have personally been interested in a case, as, for instance, by present at a meeting where the question of issuing a summons was discussed, they are disqualified from hearing the case.—Ed.]

ORIGINAL PAPERS.

OVER-PRESSURE—A COMPARISON.

By MAURICE DAVIS, M.D.

THE friends of knowledge are earnest in their desire to spread education in all directions, but many fear that teaching is being pushed too fiercely; for compulsory education, however excellent, may be purchased at too high a price, as the brain cannot work in a chilled and starving body, any more than seeds can grow in a frozen and wasted soil. Dr. Crichton Browne, in his elaborate and learned report, traces the stationary death-rate from cerebral diseases during the educational period of life (whilst there is a great reduction in all other diseases), to the fatal effect of over-pressure in elementary schools. The Registrar-General seems to bear witness in favour of that view; he says: 'But inasmuch as school work, if it be injurious to health, would probably be so by affecting the brain, and generally the nervous system, it would be well to split up these death-rates from causes other than zymotic, into death-rates from diseases of the nervous system, and death-rates from other causes. When this is done we find that the entire fall was due to diminished mortality from other causes. The rate from these fell from 2.9 to 2.5 per 1,000, whereas the death-rate from nervous affections remained unaffected. Indeed, if a second place of decimals were taken, it would appear that nervous diseases had slightly—very slightly—increased. It would appear, therefore, that while the mortality of children from all causes, and from zymotic causes, has considerably diminished, their mortality from diseases of the nervous system has exceptionally remained stationary. The general improvement has not affected this class of diseases.'

Dr. Crichton Browne then charges the system followed in elementary schools with endangering the lives of 46.1 per cent. of the children placed under the charge of the School Board. He does not however stop here, but speaks bitterly and loudly in the cause of teachers, and pleads: 'We seem to have devised a process admirably calculated for blunting their intellects and whetting their nerves at one and the same time, for making them at once more stupid and more morbid; and it is impossible to contemplate without anxiety what the effects of this process will be if it be not modified without delay. . . Irritability and feebleness always follow closely in the steps of disorders of the nervous system, and no greater misfortune could befall the country than to have a race of neurotic teachers.' These grave warnings, pronounced in so earnest a tone, suggested as likely to be interesting an inquiry into the relative prevalence of headaches in a school of similar rank, where more time is expended in study and more work done by children younger than those of the general Board Schools. An opportunity for such an inquiry is presented by the Jews' Free School, Bell Lane, Spitalfields, which educates over 3,200 children. This school, which is, we believe, at the present time the largest in the world, was founded in 1817. The house has lately been partially rebuilt at an expense of 20,000*l*. Glazed tiles are freely used; there is an abundant water supply, and the drains are flushed many times a day by attendants engaged for that purpose. The rooms, well lighted and ventilated, are, as well as

the steps and passages, swept twice a day and scrubbed and washed twice a week. This school has never been visited by an epidemic. The working hours are the same as those of the Board Schools, except that work is continued from nine to one, instead of from nine to twelve, in order that there may be time for an additional subject—Hebrew. Ninety per cent. of the pupils are either foreigners, or the children of foreigners, who, brought up to speak the language of their parents, find English altogether strange to them. Yet they have to work in the language of the country without any special instruction in English, which they pick up as well as they can, and in twenty-two weeks they are presented, according to regulations, transformed into British boys and girls, to pass their examination in the First Standard. Work proceeds regularly and steadily, and no spurt is ever put on in anticipation of examinations. On one evening in the week an extra singing class meets for the purpose of training boys to take part in the synagogue choirs. There is also a Sabbath school every Saturday (at which there is an average attendance of 500 children), besides the two hours on Sunday for religious instruction. About 5 per cent. of the children are 'kept in' for a time varying from fifteen to thirty minutes for neglecting 'home lessons,' but never without their dinners. The home lessons are not as well done as they formerly were, but there is little to complain of on this head. The time required for their preparation is estimated to be from half-an-hour to an hour and a half. There is a playground with apparatus for gymnastic exercises, but as it was calculated for 600, and is now used by some 2,000 boys, it is too small for many of the exercises, and as accidents from kicks sometimes arose, it was thought right to remove some of the appliances. From December to March those of the children who are willing to accept it are supplied by a benevolent friend of the institution with a purposely simple breakfast in the shape of a cup of milk and a hunk of dry bread. About a tenth of the boys, chiefly of the lower standards, enjoy this boon; but those in the higher grades, influenced by a feeling of independence, elect to 'suffer and be strong.' The kitchen arrangements and ample space on the girls' side enable the authorities to have the milk boiled, and so offer a warmer welcome in every respect; the invitation is therefore accepted in somewhat larger numbers. Clothing and boots are given to both the boys and girls by a generous family who have long befriended the schools, and we are assured by Mr. Angel, the head-master, that during his long experience of forty-five years, only one instance of abuse has ever been detected. In the immediate neighbourhood of the school penny dinners are offered to the children throughout the year by another institution; 120 children are accustomed to attend, 60 pay the penny, the other 60 have their dinners free: of these 120, 110 are pupils of the free school. These important privileges meet only in a slight degree the pangs of poverty from which the children suffer much. Mr. L. B. Abrahams, the vice-master, informed us that many of the boys employ the intervals in the school-work to exercise some trade for the general wants of the family, that they get very little food during the day, but have to wait until night for the principal meal, which is large or small in proportion to the earnings of the day. In order to prove that no condition of affluence can be claimed for these boys, a show of hands was asked from those who

had come to school without breakfast, when twenty-six boys responded in a class of forty-two in a high standard. As this occurred in the summer months the bounty given during the winter was not available. The regular attendance of other days is somewhat slackened on Fridays and the eve of Jewish holidays, in consequence of the family necessities demanding the services of the children to swell with their earnings the fund required for those days of unproductiveness. Dr. Crichton Browne says: 'In one school visited, the head mistress assured me that to her certain knowledge as many as 8 per cent. of the girls came to school without breakfast in the depth of winter. Cause asked, "Father out of work," "Father in the hospital," "No bread in the house," "Mother lays a-bed." The last of the answers I came to understand was often a childish euphemism for drunkenness or for the morning stupor that follows a night's debauch.' 'The consumption of alcohol which plays such havoc amongst the tender brain-cells and maims so many intellects,' is not amongst the misfortunes of Jews, however much they may be pursued by all the other associates of poverty. The children of the Jews' Free School are younger than those in corresponding standards of other schools. In February 1884, out of 1,826 boys 71 were over 13 years of age, 155 boys were in the Sixth and Seventh Standards. Thus twice as many boys were in these standards as there were boys over 13 in the school. Of the girls, out of 1,170, 32 were over 13, 125 were in the Fifth and Sixth Standards, showing that four times as many girls were found in these standards as there were girls over 13 in the school, that is to say, a fourth of the girls of low ages constituted the high classes. On the boys' side there is a Seventh Standard of 43 boys. Taking, then, the school-going population of England and Wales as 3,000,000 and the Seventh Standard pupils as 5,792, the Seventh Standard pupils of England and Wales are equal to only '1 per cent. of the whole; therefore the Seventh Standard children of the Jews' Free School, being equal to 1.3 per cent., are exactly thirteen times more than those of the general Board Schools of the country. All the teachers on the boys' side, with the exception of the head master, were pupils of the school, and there are only three exceptions on the girls' side. Not one of the candidates from the school for a Government certificate has ever been rejected. The *Jewish Chronicle* states that this school had educated one bachelor of laws, two masters of arts, twenty bachelors of arts, and 100 certificated teachers. One professor at University College claims to have been a pupil of this school, which has trained many well-known preachers and ministers of congregations, as well as teachers and head-masters of other schools. Mr. Mundella, in his speech at the festival of this institution in May, is reported by the *Jewish Chronicle* to have said: 'I find that last year the average percentage of attendance and the number on the register in England and Wales was 73 per cent., the average in the London Board School was 79 per cent., and the average last year in the school at Bell Lane was 89½ per cent., and I understand at the present moment the average daily attendance is 95 per cent. I take the average days in England and Wales and I find them to be 82 per cent., in the London Board Schools 88, and in Bell Lane 98 per cent. The average earnings in the shape of grant last year in England and Wales was 16s. 1½d., in

the London Board Schools 17s. 2½d., and the Jews' Free School 18s. 7½d.; but that applies to the year 1883-4. In 1884 the grant of the Free School was 19s. 10d. per head, the largest ever attained.' Thrift is encouraged amongst the pupils. A savings bank was established nearly thirty years ago. Deposits are paid once a week, and are returnable at any year with the interest of 10 per cent. per annum, 2½ per cent. being paid by the Moorfields Savings Bank, in which the deposits are lodged, and the remainder is supplemented by a beneficent friend, whose name is equal to his generosity, forbids the publication of his name. Seven hundred and fifty out of 2,000 have been depositors this half year. It is not paid on a larger sum than 2,000l. in a year, as the vice-master (the volunteer manager) of the bank amount involves as much labour as his leisure can accomplish. Moreover, the object is to encourage thrift in the poor, not the hoarding of money by the comparatively well-to-do. Mr. Angel, the head-mistress, conducts a similar savings bank taking on the girls' side. On approaching the classes we were careful to direct that no one suffering from headache from any cause should hold up his hand. In order to test the vigilance and good faith of the children, the head-mistress was sometimes put conversely: 'Let him who never suffers from headache hold up his hand.' It was often a slight variation; but the original object was each called out, and separately questioned with a view to test his grounds for complaint, and to elicit his opinion of its cause. Thirty per cent. of the children troubled only 'occasionally,' 'during holiday in summer,' 'from eating,' 'seldom,' 'once a month,' 'before breakfast,' 'bad health,' 'increasing weights,' still these are included in the list, as the children failed to understand the force of the word 'habitual.' About 5 per cent. suffer from headache on special days: 'Saturday, when at home as the fire' (it was elicited that the fire was not lit on 'Friday' (being a busy day at home they were away from school); 'running errands,' and 'increasing weights,' or because boys in the playground were told them about (the hours at school on Friday being from 9 to 2.30, with fifteen minutes' interval in the ground); on 'Sunday, from sitting before used for warmth in winter and cooking in the kitchen.' Some had headache two or three times a week, daily, the majority suffered most in the winter. Many could not assign a cause, but a few were accidentally struck when we had passed the 7th, 6th, 5th, and a portion of the 4th Standards. One boy said he got his headache from the *chedarim*. This is a room in which dozens assemble to study the Talmud and other works. The noise is very great, and the room being hot, crowded, small, and ill-ventilated, the atmosphere is most oppressive. The Jewish authorities had their attention directed to the condition of these *chedarim*, and are making efforts to remove the evils. A large percentage of the who attend the *chedarim*, and of these suffer from headache in the classes examined after the existence of these establishments, 45 per cent. were found to frequent them. Some boys enter at 6 A.M. until school-time, and again in the afternoon from half-an-hour to three hours in the evening in crowded places. Mr. Angel informed us that boys enter this school with a good knowledge of Hebrew, and an extensive acquaintance

Talmud and kindred works, but perfectly ignorant of secular learning. The groove in which their minds had travelled was so unlike that struck out by western teachers, that it did not necessarily lead to the rapid acquisition of knowledge demanded by the inspectors of the School Board, but that every now and then boys so trained shot with great rapidity far ahead of their fellows. Scarcely a boy would allow that school-work was the cause of the headache. We then proceeded to the girls' side, and questioned those who claimed to have headache in the same manner as we did in the case of the boys. The girls in considerable numbers, unlike the boys, did not hesitate to give as one of the causes—'Lessons'; others charged 'nursing the baby,' 'ear-ache,' 'tooth-ache,' 'summer,' 'late-hours,' 'early-rising,' 'singing-class on Tuesday,' 'hotness of the room at home.'

Amongst these, those who suffered headache rarely, say once or twice a month, attributed to falls and indigestion, amount to about 14 per cent.; exertion at home, rough play, 3; heat of room at home from coke fire, 10; 'lessons,' bad light, reading, bad sight, 14; noise from sewing-machines at home, noise of children in the house, or in the playground on Fridays, 18.

Many could not suggest any cause. When asked that they meant by 'lessons,' whether they considered the daily work of the school had produced their headaches, they replied 'no,' 'the lessons done at home,' either because the light was bad or the room too hot, or the screaming of the children, or noise from sewing machines too great—circumstances under which very few persons would delight to study. His inquiry amongst the girls, and amongst the boys also, tends to show that a large proportion of the headaches in this school is attributable not to school-work performed in school, but to that pursued under most unfavourable circumstances at home. Notwithstanding that the children recognised this action, they all clearly protested against the abolition of the 'home lessons.' Our examination terminated with the Second Standard, because the children in the First Standard are not only very young but unable to understand the questions. In reference to this state of things Mr. Mundella is reported to have said (*Jewish Chronicle*): 'I saw two Polish boys of 7 and 8 years of age, whose names could only be ascertained by the assistance of Mr. Abrahams in a variety of languages and dialects. It is marvellous that the Jews' Free School could have accomplished so much with the materials it is supplied with as compared with other schools.' We reproduce Dr. Crichton Browne's table for the purpose of immediate comparison with the results of this inquiry.

We show the Number and Percentage of Children in the different standards of Eleven Elementary Schools in London who complained of habitual Headaches.

Teachers and pupil teachers on the boys' side who, with one exception, have risen from the rank of pupils, are 48: their period of service ranges from 45, 35, 30 years, down to 6 months, making an average of 10.8 years. The time given up to extra daily work and study varies from 7 to 2 hours, the average being 3.5 hours for each of the 48 teachers. Of these—

2 have headaches frequently }
 11 " " rarely } 13
 Quite free from headache 35

Amongst these 4 are university graduates, two of whom are working for a higher degree, 4 are undergraduates working for a degree, 9 are preparing for matriculation, and many others are working for Government certificates. During the last 22 months there have been 27 absentees for 117 days, only 38 of which days could be, directly or indirectly, traced to illness caused by school work. There are 35 teachers and pupil teachers on the girls' side, who, with three exceptions, have been pupils; the period of service varies from 30 years to 8 months; average for each person, 7.9 years. The extra daily work for Government certificates and other purposes ranges from 2 to 5½ hours. In addition to this extra work, many volunteer to teach in the Sabbath schools held in these rooms; all the teachers are provided with seats.

Of the teachers on the girls' side, 6 have headache frequently; 11 have headache rarely—17; quite free from headache, 18; total, 35.

The staff is subject to alterations; some leave to improve their position; the ladies have a double inducement to change, not only to advance in their professional sphere, but in many cases to marry. The instances of teachers leaving from ill-health, or disinclination for the work, are very few. Three left from 25 to 30 years ago in consequence of consumption, from which they died soon afterwards; one was drowned 19 years ago; about the same time another died of typhoid fever; one from erysipelas 14 years ago; one from 'fever'; one left from ill-health, not finding the occupation suitable; and one, this year, from a dislike to teaching. One young lady, after 18 months' experience, abandoned ordinary teaching in consequence of frequently recurring headaches; she exchanged into another department, and now conducts the singing and needlework classes, quite free from her ancient foe. Although there be not the strictest analogy between the two classes, the one being pupil teachers and the other pupil teachers and teachers, there may be some point in comparing the percentage of headaches amongst pupil teachers generally and that presented by the mixed staff of the Jews' Free School. We extract only the total percentages from Dr. Crichton Browne's table,

showing prevalence of headache amongst the pupil teachers.

Percentage.		
Males.	Females.	Persons.
48.8	67.3	64.5
Teaching Staff of Jews' Free School.		
32.6	48.8	40.7

Recognising the delicacy of organisation in girls as the cause of excess of headache to more than double the extent of that suffered by their brothers, it is not so easy to answer the questions why do girls in neighbouring schools endure more than those of the Jews' Free School—and why the boys of this school, with so many special burdens, should yet attain greater results than their colleagues of the Board schools, with half the number of headaches, and that half, including the occasional as well as habitual headaches. No doubt the bread-and-milk given during the four coldest months of the year effect something; the clothing and shoes supplied to each child must also operate favourably, but will these advantages balance the additional daily work involved in learning Hebrew, and in 90 per cent. of the children, English also, combined with the labour and depressing influence of noise and atmosphere at the Cheder? Mr. Mundella is evidently of opinion that they will; for, in his address on Saturday, December 6, he is reported by the *Times* to have said: 'The remarkable circumstances brought about here—for there was no cry of *over-pressure* at the Jews' Free School—were the result of the fact that the Jews of West London took care that their co-religionists at the East did not starve.' The conditions, arranged in juxtaposition, stand thus:—

Special Advantages.

1. Breakfast taken by about 10 per cent. of the pupils during a third of the year.
2. Clothing and boots given to about 90 per cent.
3. Penny dinners received by 9.6 per cent.
4. Avoidance of pressure before examinations.

Special Disadvantages.

1. One additional hour per day for acquiring a knowledge of Hebrew.
2. The necessity of 90 per cent. of the pupils, being foreigners, to learn the language in which instruction is conveyed, and yet to be ready for examination at the regulation time.
3. Work at the Cheder by the boys, at the rate of from 30 to 45 per cent.

Result.

More Seventh Standard pupils, as 13 to 1.
Fewer headaches, as 31.7 to 46.1.
Larger grant by 8.4 per cent.
Greater average daily attendance, as 95 to 79.
A higher standard reached at an earlier age.

The majority of these children come from Russia and Russian Poland, where their parents have been subjected to oppression and violence; prohibited from following high-class trades, and abused for adopting those which alone are open to them; treated with contumely for neglecting intellectual pursuits, and robbed and murdered, as we have

recently seen, because their mental superiority casts into shadow that of their neighbour, and because their thrift and industry and temperance enable them to distance him. Does this struggle, instead of blunting and fatiguing with terror their ever-watchful brain, sharpen it into permanent energy and strength, in devising means for evading the fangs of the destroyer? For however hot the pursuit, they still cultivate learning, not always of the hard mother-country, but the long-prized lore of their fathers, who teach 'through knowledge the just shall be delivered'—'A scholar is greater than a prophet'—'You shall revere the teacher even more than your father; the latter brought you into this world; the former indicates the way to the next. But blessed is the son who has learned from his father, he shall revere him both as his father, and his master, and blessed is the father who has instructed his son.' Has this mental striving during centuries created a power to transmit a special cerebral receptivity to the progeny? or is it due to inherited qualities of race? Boudin and others contend for this view, and adduce strong evidence in its favour. Other observers attribute this brain power to certain habits, and dwell with force on the conspicuous characteristic of temperance. Whence comes this temperance? This is a question to be reserved for the decision of ethnologists. If neither of these be the cause, has the School Board a lesson to learn from the Jews' Free School? If headache is to be regarded as the index of endurance, we will take the boys and ask in what way are they relieved from pressure. Boys at both classes of schools have to live and study with almost equally scanty food; they have to learn their home-lessons, and dwell in equally crowded, coke-heated, and otherwise unsanitary rooms. They have cause in all probability equally to complain of strained eyes from deficient light; and are equally harassed by screaming children and noisy sewing machines; each a source of great distress even to those who have few or no home-lessons. The only advantage which the busy boys of the Free School appear to enjoy as against their friends of the Board Schools is, that they are never pressed to prepare for examinations and yet are always ready for them. As a home allowed to take his own pace will go on almost indefinitely, so a brain not forced beyond its power will accomplish with success all it is called upon to do. Our earnest thanks are due to Mr. Angel, Miss Lipman, Mr. Abrahams, and Miss Rebecca Hart, not only for their most valuable help, but for the alacrity with which they rendered it.

THE Bower-Barff process of rendering iron impervious to rust appears now to be taking that position to which its merits entitle it. It is a well-known fact that new inventions, however good they may appear to experts, have always to undergo a period of probation ere their advantages are fully appreciated, and the Bower-Barff process has but undergone the usual ordeal. Numerous medals have now been awarded the company, including one at the late International Health Exhibition, where it is stated that a considerable amount of public patronage has resulted from the display made. This process is now becoming an important factor in architectural ironwork. It is stated that a firm in Scotland have decided to adopt the process for their water-meter castings, and negotiations are in progress for introducing it into Canada and India; certain firms in the United States, where it has found considerable favour, having also entered into arrangements with the company for working the patent.

SOME RECENT ARTISANS' DWELLINGS.

HOMILY AND A CONTRAST.

By HENRY M. MAVOR.

ONAL inquiry into the requirements of degrees of the artisan classes will lead to various comparisons, which are often over- y those well-meaning individuals who make business and pleasure to try and alleviate ry of the lower rank and file of the labouring ity. The distinction here between the lower l the well-paid artisan will be purposely s by this time it is pretty well-known, or eso, that philanthropy holds but a secondary ation when providing many of the huge f dwellings which are being erected in an easing ratio. A knowledge, either super- deep, of the value of land in busy centres nishes any idea of being satisfied with a a 2 or 3 per cent. return, and unless the s voluntarily forego the profit on an ordi- nness transaction and substitute sentiment nage, the lower rank must remain in their nt obscurity,' and be as content as they l the good wishes of those who secure the l then promptly cater for the better-paid l can afford to pay a rent which shall give in some cases, far exceeding 5 per cent. npetitive age only individual philanthropy pected, and isolated charity is powerless to h co-operative misery. That misery may co-operative is conclusively shown by the ed efforts of many of the mass to prevent es from rising in the scale of comfort and ss. Those referred to not only refuse to selves (except in a literal sense) or helped, but with Oriental resignation o the depressing influences of their sur- s, and even consider themselves fortunate aintain a dead level of squalor and semi- r, the outcome of apathy and despair. A point may be instanced in a medium-sized llings not a hundred miles from London Some few years ago these buildings were a fairly substantial manner, with reason- ation to the requirements of a class below n, viz., those in irregular receipt of wages gs which rarely exceed one pound per o as not to swell the current expenditure ; no caretaker appointed to the block, and ts were left to look after themselves as best d. This 'go as you please' principle re- a down hill handicap, in which the price pid that in a short time it was found neces- e sanitary inspector to condemn the block nce and unfit for habitation. Upon repre- s being made, however, the order was held ice to give the inhabitants a chance to pull id under the able supervision of an ener- etaker the unruly and malevolent were expelled, and those that remained were o pay attention to the decencies of life ut to the regulations laid down for their the result being that the block now is in ng order. But the large companies paying ., and owning a large reserve fund, have othing to do with this class of tenant, and etter class that is under consideration at

One of the most noticeable undertakings of this description is the erection of five large parallel blocks in Petticoat Square, under the direction of Colonel Haywood, the engineer to the Commissioners of Sewers. In some respects, although in a squalid neighbourhood, these buildings are remarkable for the expenditure and general air of superiority, forming a strong contrast with the surrounding quarters. This, however, is a wholesome example, and, as the funds are provided by the Corporation, the scheme is placed on a different footing to those of an ordinary character.

To begin with, the plan is liberal in its space for staircases—i.e. one staircase serves only two tenements of three rooms each on each floor, and immediately opposite the staircase landing is a large scullery or wash-house, provided with ample sink space and a copper, this wash-house being common to the two tenements. There is a sense of elbow-room throughout, which is often found wanting where pounds, shillings, and pence have been the first consideration. The fact of the staircase serving two instead of four tenements (as is often done, without detriment to the general plan) tends to give more seclusion to the occupiers; and, although an expensive feature, it is one that is generally appreciated by the superior class of tenant. In some portions there are shops on the ground floor, with an extensive basement suitable for storage, but not for habitation. The 'fitments' are well arranged and plentiful, the zinc-lined coal-box in the lower half of the living room cupboard being ingenious and useful. The ventilation of the food-cupboard also is a point which could be copied with advantage. The exterior is in places expensively treated with moulded bricks, and the panels and pediments contain some well-designed and executed emblems and the City arms. Fire-proof floors have been used throughout, and the walls and ceilings are finished in hard cement, such as Keene's or Martin's, which is far more expensive than ordinary plaster. The roof, as is often the case, is utilised as a drying and play-ground. One block is finished and ready for occupation, and the remainder are fast approaching completion, and it may be said that these buildings can hold their own against any so far called into existence. The cost of the works will be about 64,000*l.*, and the return upon the outlay must necessarily be very small when compared with a block built for profit. Without going into close calculation the work looks like costing certainly 8*d.* per cubic foot, whereas many large recent blocks have been sufficiently well built for 6*d.*, thus there is a difference of 25 per cent. in the capital outlay.

Another point in the class distinction referred to may be cited in the death-rate as applied to the tenants of the higher rented buildings. It is frequently pointed out that the death-rate is exceptionally low in these cases, but be it remembered that these are *desirable* tenants, a selected class, and selected with commercial discrimination, the able-bodied, well paid, and well fed. The lame, the halt, and the blind find no resting-place, no encouragement here. The individuality of the Samaritan is within circumscribed limits, but happily it is not for all to 'pity and pass on.' Improvidence and drink are factors in the calculation; but it is not so much the fault of the individual as of the age; there is barely room for all to live; to let live is a consideration deferred, and unfortunately too often deferred until the necessity to live at all becomes a doubtful question.

We will now turn to a very opposite case—viz., a block in Cartwright Street, Royal Mint Street, where the East End Dwellings Company are erecting some buildings on a site recently acquired from the Metropolitan Board of Works. The area is about 32,000 feet super, and was purchased for 4,600*l.*, or 2*s.* 10½*d.* per foot. This is a price sufficiently low to give a start on an economical basis. Messrs. Davis and Emanuel are the architects, and the cost is a little under 14,000*l.*, the cost per cubic foot being about 5½*d.* The building is one long rectangular block with a gallery to each floor, at the back running the whole length. It will be seen that an entirely different class of tenant is being here provided for, and the plan and style of building are adapted accordingly, for it is only in the cheaper plans that galleries are now used. It appears that the promoters will be content with a very small return upon their capital; the advantages thus offered to the labouring poor will be great, and worthy of being more extensively followed. The plan is so designed that the rooms can be let off in any number from one to five. The latrines both for men and women are placed on the same landing, and side by side, and this seems to be the least satisfactory point in the scheme. A sink, common to several rooms or tenements, adjoins these latrines, and although this single sink arrangement seems to be a limited accommodation, it will probably suffice for this class of tenant, as the washing will be done in a separate and detached building in the rear. This general wash-house is provided with eight coppers and numerous washing troughs. The general system of sanitation has been most carefully and consistently elaborated and money freely and well spent in this direction. The rain-water from the roof is utilised to add to the flushing of the latrines, which are made of concrete and lined with asphalt, instead of being the ordinary manufactured article. Due provision is made for ventilating the soil-pipes, and trapping and disconnecting the outlets at each floor, and six manhole inspection chambers are provided between the house-drains and the sewer. It is evident that although economy has been the guiding principle throughout, that in order to do the right thing in the right place the necessary expenditure has not been withheld, but the legitimate cutting and saving has taken place where it could safely be done. A somewhat unusual feature is the non-fire-proof construction of the floors; but as a gallery-plan means an ever safe exit in case of fire, a wooden floor of the description used is not of so much importance as it would be in a building planned on a different system. The fittings are of the cheapest kind, the fireplaces are of black Staffordshire bricks, with an iron shelf, so that this latter item is safe from the destructive hands of a tenant who is in temporary (or permanent) want of firewood, for instances are not otherwise wanting of such handily placed material being put to the use suggested. At one end of the block, communicating with the caretaker's residence, there is a club room provided, although the experience hitherto gained goes to prove that a club room is not used or appreciated by the tenants to anything like the extent that it either could or should be. It is very difficult to see why this objection to sociability should exist, but such is the case, and this class is conservative in this respect. The roof here is not utilised as a ground space, probably on account of expense. Progress

is being made with a portion of the interior fittings of some of the rooms, and, as usual, inquiries are already being made by intending tenants.

Taking all the circumstances into consideration it may be safely said that this scheme is a strongly-marked advance in the direction of housing the very poor, a question considered by many (evidently students of human nature) to be without a solution, but the solution bids fair to be within a negotiable distance if experiments of this kind are to be repeated. We have here a cheap site, cheap building, and a small return, by which means the tenants can be housed at a rent which does not bear the usual disproportion to their earnings. Theory and practice are ever widely divergent, and never more so than when dealing with questions affecting the many, but here we have the theory of five per cent. accommodating itself in practice to a much lesser amount, and this principle must be the means by which it is to be hoped that the gap between progress and poverty may be reduced. There is here great scope for abnegation; the demand is unlimited; will the supply be forthcoming? will human nature abhor the vacuum? If the 'building society' principle be added to the system here suggested, a still further advance would be made, and one of the great social questions of the day would be in a far way to be settled, and settled in a way that would go far to remove the prejudice which exists in the mind of the recipient of benefits which are admitted but not readily recognised by those *beneficiaries* immediately interested. Charity is a cloak which covers a multitude of sins (and sinners), but it will not shelter the independent homeless unless it be a literal cloak and in itself an impenetrable disguise. To render it such may be possible, and a possibility may, by discretion and tact, be brought within the bounds of probability.

MUSEUM OF HYGIENE AT TURIN.—A Museum of Hygiene, similar to the Parkes Museum in London, will shortly be opened at Turin, and extensive purchases in the health department of the International Health Exhibition were made by Dr. Pacchiotti, who is one of the chief promoters of this useful institution. Amongst the principal objects that have been already brought are the two models of temporary hospitals for contagious diseases, by Dr. Villa and Signor Maggi, of Misanto; the portable apparatus for gymnastics for the use of families, of Signor Campasini, of Reggio Emilia; a model of a furnace for cremation by the Milan Society for cremation; three urns to contain the ashes after cremation, of C. Riva, of Milan; and an apparatus for washing and disinfecting automatically urinals, invented by Signor Mottura. The following donations have been made to the museum by the various exhibitors: Signor Buscaglione, of Turin, a model of his own for disinfecting clothes, &c.; the new Waterworks Company, of Genoa, the model of the great artificial reservoir of the Deferrari-Galliera aqueduct; Signor Bertolotti, the models of houses for the working classes at Bologna; Signor Fasini, of Milan, the plans of the new working men's quarter at Porta Vittoria; Signor Pignocchi, the plans for the water supply to Osimo; the 'Società di Mutuo Soccorso,' of Treviglio, drawings of the co-operative kitchen established in that town; and lastly, the admirably executed collection of wax models of edible and poisonous fungi, comprising no fewer than 288 specimens, made by Cav. Maestri, and given by the King.

At the International Health Exhibition, Gold, Silver, and Bronze Medals have been awarded to the Patent Sanitary and Ventilating Appliances of Mr. W. P. Baile, of Glasgow,

NEW DEPARTURE IN HOUSE DRAINAGE.

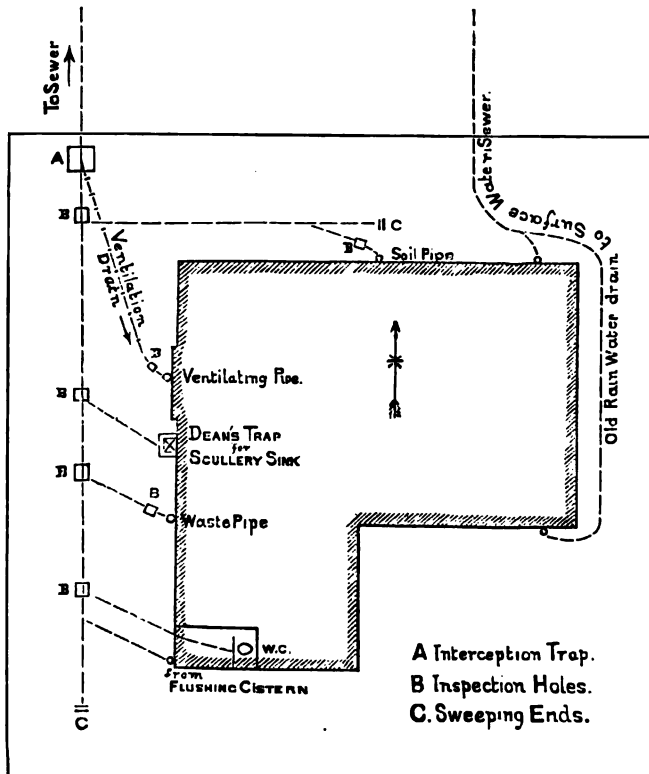

By D. J. EBBETTS.

I had to design the drainage of a detached house in the suburbs of London, in which I proposed to improve if possible upon the ordinary arrangements. Three of the principal such arrangements I understand to be 1. That the house-drains should be detached from the public sewer by an air inlet trap. 2. That the highest point of the drains be a ventilation-pipe taken up to a safe height; and 3. The soil-pipe should be disconnected at foot by an air inlet trap should be carried up full bore for ventilation.

If these three points in mind it will be seen the system acts as it is supposed to do, you have air entering by the inlet traps and passing down the drains and up the ventilation-pipe in the one, and up the soil-pipe in the other.

dangerous; as it is often impossible to place such traps at any safe distance from doors, windows, and ventilating gratings. Further, it occurred to me that if I could safely omit the traps at the feet of soil and waste-pipes, I should facilitate the discharge of their contents. The problem, therefore, which I put to myself was how to design an arrangement that should allow the ventilating currents to travel in the same direction as the water in the pipes and drains; that would not require any *open* traps; and, if possible, that would allow of the omission of some at least, of the usual traps.

What I did in my attempt to solve this problem was this: first of all I placed a disconnecting trap on the drain at the point of departure from the premises, and carried up a pipe-shaft from this trap to the surface, and securely covered it over with a stone, &c. From the *upper* part of this shaft I led away a 4-inch branch and connected it with a 4-inch ventilation-pipe. A great deal depending upon this pipe, its position was carefully selected. As the flue from the kitchener is placed in an external wall,

It appears to me to be a very unscientific arrangement, for every time you discharge water in the house into either the soil-pipe or drain, you are at the same time the ventilating current in each. I have taken so much pains to establish the system, the open traps which I have referred to, and which are instantly charged with fresh sewage, are the most offensive. That this occurs at the expense of an assumption on my part; it is a fact that is proved in my practice as well as in that of other town houses, too, with cramped yards, it may be not only offensive but even

advantage was taken of its warmth by fixing the pipe against it. The pipe was carried up to a safe height above the tall chimney stack, and was finished with a fixed extraction cowl.

Having settled the ventilation or extraction-pipe, I looked for suitable air inlets. I found a soil-pipe on the north side of the house receiving the outgoing of a valve w.c. apparatus, and the trapped wastes of a housemaid's sink, and a bath, all on the first floor, and on the west side a rain-water pipe, taking the trapped waste-pipe of a fixed lavatory on the same floor. These two pipes I made the air-inlets of my

new system, and as I determined that no air should pass *up* these pipes, I was able to connect them to the drains with quadrant bends without the necessity of using traps.

Since the work has been finished (more than six months ago) its efficiency has been tested on many occasions during different conditions of the atmosphere, but it has always been found to act admirably, there being on each occasion a steady draught *down* the soil-pipe &c., and *up* the ventilation-pipe, and it was noticed that every discharge of the soil-pipe, instead of retarding the ventilating current, actually and appreciably assisted it, drawing in fresh air at the upper end of the soil-pipe and driving the foul air before it and up the ventilation-pipe.

By reference to the plan it will be seen that inspection holes are provided at the feet of soil, waste, and ventilation-pipes, and also at all junctions; each branch of the drain has a sweeping end, and the main branch is automatically flushed by a Field's cistern. The drains are all 4-inch pipes, laid to a fall of 6 inches in 10 feet, and the interception-trap is a Kenon's (Doulton's) 4-inch trap with a 9-inch body. Should it ever be necessary to sweep any obstruction through the drains, the size of the shaft will permit of its being readily extracted.

What I have done may possibly be no novelty, though it is new to me; but, whether it has been done before or not, it appears to me to be more simple, scientific, and effective than the plan in general use.

MR. P. E. CHAPPUIS, of 69 Fleet Street, has just received from the Lord Chancellor a Royal Warrant, appointing him manufacturer of Daylight Reflectors to the Queen. Mr. Chappuis, who was the inventor of those useful appliances, has during the many years he has been in business proved a benefactor to thousands, who by their assistance have been enabled to follow avocations for hours by daylight that otherwise would have been carried on in gaslight, and to the detriment of health.

SANITARY ASSURANCE ASSOCIATION.—The first of a series of Lectures on Sanitary Subjects was given on Nov. 26 at the Parkes Museum, Margaret Street, W., when Mr. Henry Rutherford, barrister-at-law, lectured on 'Sanitary Assurance from a Householder's Point of View.' Dr. R. Farquharson, M.P., presided. Mr. Rutherford began his lecture with an allusion to the apathetic attitude of a large portion of the public in regard to sanitation. He spoke of the absence of efficient sanitary arrangements in large houses as well as in smaller dwellings, and referred to his own experience as a householder who had sought the advice of the Sanitary Assurance Association, which led to his ascertaining the fact that, instead of the drain from his house going into the main sewer, as he had imagined, it ran in an opposite direction, and discharged itself into his neighbour's garden. And, further, that the drain was not in any way disconnected from the house. In speaking of the Association he said that sanitation had become a science in itself, only to be mastered by special study and actual experience. He did not recommend the compulsory inspection of dwellings: the intrusion into our houses of officials who merely came to see if any evils existed was a form of paternal government which we were not as yet disposed to encourage. At the same time he suggested that every house ought to possess a sanitary certificate, obtained from a properly qualified person, and registered like a vaccination certificate.

MR. BUCHAN has just been informed that his Disconnecting Traps and Ventilators and also the Grease Traps have given the utmost satisfaction since they were introduced at Balmoral Castle.

LIGHT AND AIR IN HOUSE PLANNING.

By G. H. BLAGROVE, A.R.I.B.A.

'WHERE the sun does not enter, the physician does,' says an old proverb; and the value of sunlight as an auxiliary of health is as well understood by the Faculty of Medicine, as is that of pure air. Considerations of aspect in house planning, however, do not appear to be so frequently borne in mind as we might be led to expect. In town houses, indeed, when they are not detached, it is impossible to choose for oneself the situation which a dwelling shall occupy with respect to the points of the compass, since the directions of our streets have already been determined by other considerations than those of aspect. In London, and in other large towns, it unfortunately happens that the directions of the streets are, in the majority of cases, almost due north and south, or due east and west. The best possible conditions of lighting are not obtainable under such arrangements, particularly in the latter case, where the houses face north and south.

A painter or sculptor prefers a north-lighted room for his studio; but, with such exceptions, it cannot, we think, be disputed, that north-lighted rooms are objectionable for habitation during the day. An aspect which admits no ray of sunlight from morning until night, must exercise a depressing influence upon health and spirits. When the choice lies between north and south, we should therefore prefer a south aspect for those rooms which are in constant use, and these, in small houses, are the dining rooms.

Although, in the quaint phraseology of Dr. Fuller, of Sarum, 'a south window in summer is a chimney with a fire in it, and stands in need to be screened by a curtain,' yet the periods of oppressive heat are few and far between in this climate, and the inconvenience of a south aspect is not experienced during the greater portion of the year. A bay, semi-hexagonal upon plan, in which the central window can be completely closed by means of a lifting shutter, is well adapted for a south aspect. Venetian blinds inside a room, although they effectually exclude the light, do not afford much protection against the heat of a midday sun, because the glass of a window offers an extensive surface for the reception of heat, and the transmission of it into the interior of a house. Louvred shutters, hinged or sliding, or Venetian blinds *outside*, are the most serviceable, and the latter, when drawn up, should be entirely protected from the rain by boxings.

In planning small terrace houses, the conditions are, of course, very circumscribed. It is difficult to suggest many improvements upon the ordinary arrangement, in which the house is entered by means of a passage on one side leading to a staircase beyond. The principal room upon the ground floor is in front—the increased width required for the two flights of the staircase reducing the size of the back room to a smaller dimension. A few steps lower, on the way to the basement, we generally find a third, still smaller room, built out beyond the back-frontage line. Over this small room, on the level of the first landing, there is usually a lobby or commutatory, leading to a W.C. and lavatory; but in small houses, the lobby and W.C. are often shut off by a door, and there is, therefore, no staircase window until we reach the landing above the first floor.

We are aware that popular prejudice is in favour of placing the best rooms of a town house towards the street, and that aspect is thus too frequently sacrificed to prospect, because architects and builders are obliged to conform to the predilections of those for whom they cater. If that attention to aspect, which sanitary considerations dictate, more frequently prevailed, we should sometimes see the principal rooms of a small house placed at the back, and the staircase brought to the front, by which some small sacrifices would be counterbalanced by certain advantages, not wholly unworthy of notice.

With the staircase in front, the advantage of a good entrance hall is obtained, with more light and air than in a narrow passage. Beyond the staircase, a narrow passage leads to a lavatory and W.C. in an outbuilding. The small third sitting-room is sacrificed by this means, but the loss is not a serious one. Such a room, built usually with its walls only one brick thick, is much exposed to vicissitudes of temperature, is practically uninhabitable during the winter, and as a matter of fact is used only for boots and lumber. The W.C., formerly on the first landing, where it was too conspicuous, and often offensive, is now in a more retired situation, and a fine staircase window is obtained in the front of the house, on the first landing. The principal drawing-room, extending throughout the whole width of the house, is at the back, and leading off from it, over the outbuilt lavatory and W.C., can be either a conservatory, or a small room, as card or chess room, completing the suite of three drawing-rooms. The outbuilding may, under this arrangement, be carried up to the topmost storey, if desired, since it no longer blocks the staircase, and it can be made available for dressing and bath-rooms, leading off from the bed rooms above. It is usual in planning small terrace-houses to place the entrances on the same side in each house; partly because there is less annoyance from sound when a passage is interposed in every case between the adjoining ground-floor rooms, and partly because there is supposed to be more privacy when the entrances are kept apart. We may, however, venture to point out one or two advantages which would accrue from placing the entrances in juxtaposition.

If the entrances of adjoining houses are brought together, the various parts of their plans will be in reversed order, and in a terrace, the blocks of outbuildings at the back will be coupled together. The result will be that the distance between these blocks will be just double what it would be if each outbuilding stood singly, and that the actual width of the light and air court, above the division walls of the gardens or yards, will be doubled for the benefit of each house—an important consideration. Another result of coupling the blocks of outbuildings would be the substitution of one party wall for two external ones—a measure of economy that ought to commend itself to the approval of all speculators in building.

Some of the small areas upon which inhabited rooms in town dwellings are dependent for light and air, are often productive of conditions prejudicial to health, and the limit prescribed by legislation of 200 feet superficial, is subject to no restriction as to proportion, which is certainly to be regretted, since 20 feet by 10 feet is a very different thing from 20 feet by 5 feet. Besides this, such areas are often carried to heights which render the access of a proper amount of light and air impossible. There is always a tendency, in these areas, for the air to become stagnant, especially in its lower strata. To

remedy this, a device has been employed which we commend to the notice of all who are desirous of securing sufficient ventilation in confined areas. It is exceedingly simple and inexpensive, and it deserves mention from the fact of its being so frequently omitted in the construction of town dwellings. It consists in connecting one open area with another by means of a pipe or channel passing under the floors of the basement rooms. If it pass under a kitchen, so much the better, for the heat of the fire will increase the draught, and promote a free circulation of air.

Rooms in a basement which is sunk far below the level of the ground are never healthy, even when they have wide areas in front of them, which they frequently have not in London. It is to be regretted that some of these rooms, so scantily supplied with pure air as many of them are, should still be permitted to be used as sleeping apartments for domestic servants and others. We are glad to note that in many of our modern suburban residences, the ground floor is raised to a level of about twelve steps above the street footway. By this means, the so-called basement is more than half out of the ground, and the front 'breakfast room' serves for dining. Probably most persons will not mind the trouble of going up a few extra steps to their front door, if by that means their servants can be relieved from passing the greater portion of their existence under ground.

That a basement should be thoroughly ventilated is of the greatest importance, because the tendency is, especially in the cold weather, for the air to rise from thence to the upper portion of a house. It would be better if cellars, or other open spaces, could be contrived beneath the floors of all inhabited rooms. In any case the floors should not be less than eighteen inches above the level of the earth beneath. Floors may be constructed with joists and floor boards, or, on the old Roman plan, with tiles, having hollow spaces beneath for the free circulation of air. Floors formed with wood blocks, laid upon concrete, are now coming into use, but it is to be feared that they are prone to harbour damp, partly from the thickness of the blocks, but chiefly from the absence of ventilation beneath them.

THE Rain-Water Separator, patented by Mr. C. J. Roberts, of Haslemere, Surrey, and which we have had occasion to favourably notice in these columns, obtained a silver medal at the International Health Exhibition, Class XXI. The object of this ingenious contrivance, as stated in our detailed notice previously given, is to separate the dirty water from the clean, and the way in which it is attained is a very successful attempt to overcome a long-standing difficulty. It is, however, *not* a filter, but solely a separator. It is self-acting, and directs into a waste-pipe or foul-water tank the first portion of the rainfall, that washes off, and brings down from the roofs snot and other impurities. After rain has been falling for a certain time, the separator catches and turns the pure water into the storage-tank. We are informed that the apparatus is proving a success in London.

WATER ANALYSIS.—At a meeting of the Council of the Sanitary Assurance Association, at 5 Argyll Place, W., on Monday, December 8, Sir Joseph Fayrer, K.C.S.I., F.R.S., in the chair, it was resolved, on the motion of Mr. Mark H. Judge, A.R.I.B.A., seconded by Dr. George Danford Thomas, 'That, in addition to the analysis of water in connection with the sanitary surveys of the Association, it shall in future undertake to analyse any samples of water forwarded to the Association in accordance with instructions to be obtained of the Secretary.'

DEEP DRAINAGE AND SEWAGE PURIFICATION IN THE BLACK COUNTRY.

(FROM OUR OWN CORRESPONDENT.)

[Second Article.]

In the first article on this subject (published in the September number of the *SANITARY RECORD*) we endeavoured to show how, through the passing of the Rivers Pollution Prevention Act, and in other ways, the question had been brought into prominence, and local authorities compelled to take active measures for dealing with the serious and extensive evils arising from the want of drainage at that time generally prevailing in the Black Country district. We also referred to the action taken by the South Staffordshire Mines Drainage Commissioners in respect of surface drainage, and to the physical formation and geological peculiarities of the district. In this article we had purposed detailing what has been done by the midland metropolis, Birmingham, which borders upon that district, in the direction of the collection, treatment, and disposal of the sewage of its 8,500 acres and 420,000 inhabitants. During the interval, necessitated by congressional demands upon space, however, the subject has been so fully and ably dealt with by Mr. Lawson Tait (chairman of the Health Committee of the Birmingham Corporation) in a paper read at the Social Science Congress, and published in the October number of the *SANITARY RECORD*, that this branch of the subject may very well be disposed of in few words. Years ago, when the houses in the 'hard-ware village' were less closely packed than they are now, the old-fashioned but still much used midden, combining closet and ashpit, fairly met the requirements of the inhabitants, and the matter collected could be conveyed with little cost to the not far distant agricultural land, where its employment as manure ended the whole matter. As time went on the houses increased and the sites for sewage tips became less numerous and more difficult of access. The pan system was gradually introduced, and the sewage treated in various ways which have developed into a scientific method which brings the resulting nuisance down to as low a point as possible. At the end of last year the number of pans in use in Birmingham was 37,287, and the carrying out of the necessary work involved the collection during the year of 1,847,061 pans and 72,404 loads of ashes; in addition to the emptying of 19,708 privies and ashpits constructed on the old system, and the removal of 56,562 loads of ashes and other refuse therefrom. The stuff thus collected is dealt with by the poudrette process, by which the excreta is dried to a powder, which is very valuable and much sought after for manurial purposes; and on the Sewage Farm at Saltley, where some 220 acres are employed for the purpose of purification by lime and tank precipitation, the sludge being dug into the land, about 240 of the 500 tons of sewage collected in the borough in a week is at present treated by the 'dry' process. The average flow of sewage, storm water, &c., is said to be nearly 14,000,000 gallons per day, and the amount of sludge to each day's sewage is 550 tons, representing about 80 tons of solid matter. Additional land has been secured for the purpose of extending the farm, which has also to deal with the sewage brought on to it from

towns and places outside Birmingham, but within the district and under the control of the Birmingham, Tame, and Rea District Drainage Board, in addition to that from Birmingham proper which at present cannot be dealt with in any other way. So that, on the whole, Birmingham may be said to have manifested a laudable disposition to do its best to overcome the many and serious difficulties by which the question of sewage treatment and disposal is surrounded in respect to a town of its size, population, and situation, and to have not only set an example for other towns to follow, but to have also earned the right to call upon them not to render its efforts towards the purification of the surrounding streams and watercourses nugatory by their own delinquencies and shortcomings.

Wolverhampton, though, like Birmingham, scarcely in the strict sense of the word a Black Country town, or only partly so, covers a large area, and has a large and important population to provide for in sewerage matters. It is by no means so forward in this respect, however, as it should be, considering that it has the interests of something like 80,000 population to look after, with 14,469 inhabited houses, an area of 3,440 acres, and a rateable value of 246,000*l*. The midden system very largely prevails, and some parts of the borough are still unprovided with sewerage of any sort. The first serious attempt to deal with the question was in 1858, when a comprehensive scheme was formulated, and, with several other schemes, formed the subject of consideration for some years. Then the Barnhurst Farm was purchased for the treatment of sewage by broad irrigation, and at subsequent periods portions of the borough were sewered, the total cost to the present time of the existing system being 129,938*l*. In 1883 Mr. Edward Pritchard, C.E., presented a report as to the cost of carrying out a separate system for the unsewered part of the borough, and of additional works required at the sewage farm, the total cost being estimated at 44,100*l*. Nothing was done, however, and in February last a further report was submitted by Mr. G. E. Thoms, C.E., the borough engineer, for sewerage the Rough Hills district, an area of 900 acres, part of which was then drained into the Stow Heath brook; and the cost of draining to the sewage farm that part of the district in question which drained into the brook, was estimated at 2,150*l*. Subsequent to that a report was furnished by Mr. Pritchard dealing with practically the same area, in which report the cost was increased to 3,600*l*. As part of the Rough Hills district could not be drained to Barnhurst, the borough engineer suggested the obtaining another site for sewage treatment for that part of the borough, and recommended Highgate Common, situate a distance of nine miles. Matters went on in this way until the Corporation were served with notice of legal proceedings under the Rivers Pollution Prevention Act, by Messrs. Elwell, of Wednesbury, and also by the Bilston Commissioners for polluting the Stow Heath brook, a tributary of the River Tame. The pollution was practically admitted, but the Corporation appealed for a suspension of the provisions of the Act affecting the case during a reasonable period, to allow of a scheme being formulated which might meet the wishes of the complainants. Mr. J. T. Harrison was sent down by the Local Government Board as a Commissioner to enquire into the circumstances, and he was informed that a sewerage scheme for the locality in

question, providing for the sewage being sent in the main sewers to Barnhurst, had been prepared, that plans for carrying it out were in course of preparation and were expected to be ready for submission to the Local Government Board within six months, for which period it was desired the Act might be suspended as affecting Wolverhampton. The inspector generally approved of the scheme, which is that prepared by the borough engineer, and the time asked for was granted. This scheme is part of a larger scheme prepared by Mr. Thoms, providing for drainage to and additional works at Barnhurst, the sewerage of Rough Hills, Merridale, and Newbridge districts, and intercepting and outfall sewers for the part of the district proposed to be treated at Highgate Common, at a total cost of 63,400*l.*, which, added to the amount already expended, brings the total sum for sewerage works in connection with the borough of Wolverhampton to 193,338*l.* The work seems to have been done in a piecemeal fashion, and has, doubtless, cost more than one bold comprehensive scheme would have done. It may be necessary to recur to Wolverhampton in another paper. But for the present it can well be left, with the general observation that it does not appear to have added very much either to the general or scientific knowledge of sewerage disposition and treatment, and that it is still behind many other towns of lesser importance in the manner in which it has dealt, and is dealing, with this important question.

Willenhall, a town of some 18,500 inhabitants, situate in the Black Country, near to Wolverhampton, under the jurisdiction of a Local Board of Health, and containing an area of 2,168 acres, has also been in great trouble in reference to its pollution of the river Tame, and in January last, in order to avert costly legal proceedings which were threatened by the Birmingham Corporation, by the National Arms and Ammunition Company, of the same town, and by Messrs. Elwell, of Wednesbury, who have a vested interest in some water-course, known as Elwell's Pool, which is fed by the Tame, it was found necessary to take some decisive steps in the matter, and it was agreed that pressure be brought to bear upon the owners of some land required for irrigation purposes—this being the system of treatment proposed to be adopted. One main sewer through the town, it was considered, would be sufficient, and some demur was made to any scheme being carried out which would cost anything like fifteen to twenty thousand pounds until every means had been tried for doing what was required at a less cost. Eventually Mr. Baker, the surveyor, was appointed engineer to the scheme, with instructions to prepare the necessary plans, surveys, and specifications for carrying out the work.

The Corporation of Walsall was one of the first public bodies in the Black Country district to recognise the gravity of their position as an unsewered town in regard to the pollution of streams and watercourses. And they have carried out a system of sewage purification by broad irrigation and intermittent filtration, at a cost of about £53,000, in a complete and satisfactory manner, so far as Walsall proper is concerned, while other towns have been thinking about what they should do. And it is now seeking the sanction of the Local Government Board to a further expenditure of about £27,000, for completing the scheme in the area within the jurisdiction of the Corporation by the sewerage of the

adjoining district of Bloxwich. The history of the proceedings which culminated in the completion of the Walsall Sewerage Scheme is of some little interest, and affects similar works now being or about to be carried on in three or four neighbouring towns. But it is too lengthy to enter upon here, and must be reserved for another article.

A HISTORY OF A HOUSE-DRAIN.

THREE sinks and a wash-hand basin in different floors of the house communicated with the drains, two sinks being protected by bell-traps, with the bell generally absent, and the other two by syphon bends in the pipes. The waste-pipes of three cisterns entered the drains, whether trapped or not trapped is not known. The water company, philanthropists without any intention of being so, demanded some years ago a disconnection altogether of these pipes with the drains. This wholesome change suggested the separation of the sinks from the drains, and the substitution of syphons for bell-traps in the areas. After all this had been completed, the house was considered to be in a first-rate sanitary condition, and the tenant felt very secure, as, on purchasing the lease of the premises some twenty years before, he had the old brick drains removed and glazed pipes put in their places by a builder who was considered an excellent workman.

About two years ago rats were found in the house, but, as the sewer in the side street had been recently opened, it was believed that some of these beasts had escaped from the sewer and changed their lodgings in favour of a little room F, opening into this street. Many were caught, but more came on, committing serious depredations in the pantry and flooring, literally—

**'And down through the ceiling, and up through the floor,
From the right and the left, from behind and before.'**

At last a builder was sent for. He did a deal of digging and bricklaying and slaughtering of rats

while the family were away, but all to no purpose. Then a more knowing man in the specialty of drains was employed. He unearthed the whole system, and found the valve-trap A was held open by a piece of wood that had floated down the sewer, so that the rats had free access to the drains, from which they reached the roof of the small building in the garden through the rain water-pipe B, which was directly continuous with the drain. Having reached the roof, as they were seen to do by a neighbour, they spread themselves as they listed over the ground floor and basement.

On examining the drains it was found that two joints, CC, had never been cemented, that some small pipes near the front sink were crushed, and that the inclination of the whole drain was in a backward direction. All these defects have been corrected, a syphon-trap and a ventilator interposed between the sewer and main drain of the house, a tall pipe extending beyond the roof inserted at the termination of the drain, and the short water-pipe E made to deliver its rain water on the open. After capturing a few remaining rats they were seen no more; and now it is to be hoped the occupiers of the house are not only *secure* but also *safe*.

THE TORQUAY WATER SUPPLY.—It has been very properly laid down, as a principle upon which sanitary authorities should act, that no effort should be wanting on their part to ensure an ample supply of water from a source beyond suspicion and free from the possibility of contamination. This, we learn from the *Western Morning News*, is exactly what has been done by the Torquay Local Board, the water supply for that place and the surrounding towns being obtained from the natural watershed of Dartmoor, about eighteen miles distant. The completion of the second storage reservoir, at Tottilford, after encountering serious difficulties, is a matter for congratulation. Should no further mishap occur, and the rainfall be abundant during the next few weeks, the new reservoir will soon be full. It has a holding capacity of 200,000,000 gallons, in addition to the 100,000,000 gallons contained in the old reservoir, situate below it in the same valley. The two reservoirs are, therefore, capable of storing an aggregate of 300,000,000 gallons. They are constructed at an altitude of 700 feet above the sea level, and the water is conveyed thence by gravitation through a series of perfectly-closed mains and distributed into every part of Torquay, as well as to Newton Abbot, St. Mary Church, and Cockington, to a population of upwards of 40,000. So abundant is the water that a constant supply is given, and assuming 25 gallons per head as a sufficient daily supply, the reservoirs are capable of impounding ten months' supply for the whole district, so that any future period of drought will be able to be met without the least anxiety. The total cost of the new reservoir has been about £31,000, being several thousand pounds over the original estimate owing to the leakage discovered in the dam and its rectification; and altogether, since 1858, the authorities of Torquay have spent £120,000 in providing a pure and abundant water supply. The softness and purity of the water is shown by the fact that the total solid constituents amount to only 4.56 grains per gallon, and that it is perfectly free from organic and mineral impurities of every kind. The value and importance of these figures will be better understood by a slight comparison. The water of the Lake of Geneva contains 10.64 grains of solid constituents per gallon; the water supplied to some parts of London 21.66 grains; and the water supplied to New York, which is regarded by American chemists as possessing remarkable purity, contains 5.73 grains per gallon.

THE SANITARY RECORD.

DECEMBER 15, 1884.

The Editor will be glad to receive, with a view to publication, announcements of meetings, reports of proceedings, and abstracts or originals of papers read before the members of any sanitary or kindred association.

Local Authorities throughout the country would confer a favour on the EDITOR of the SANITARY RECORD if they would forward to him all published documents relative to Water-supply, Sanitation, and Health matters generally, which come under their notice. He would also be glad to receive reports from Engineers of Waterworks, Sewerage Projects and Domestic Drainage Improvements for notice, comment and illustration.

A WORD AS TO RESERVOIRS.

THE notices of intended applications to Parliament in the *London Gazette* are not as a rule very attractive reading, except to those who are interested in observing how hope springs eternal in the promoter's breast. There seem to be this year, however, an unusually large number of applications with regard to water-supply. Nine corporations and eighteen companies are asking for powers to extend their districts, to establish new works, and especially to construct new reservoirs, the descriptions of which the framers of the notices appear to pen with a certain unction. Now looking to the water famines which several of our great towns have narrowly escaped of late, and from the danger of which some of them do not appear even now to be free, the importance of a largely increased storage of water for the wants of large urban communities can hardly be overrated. But there are dangers in these huge reservoirs of millions of gallons of water, as the bursting of several of them in days gone by has amply shown us; and we confess to a certain feeling of apprehension as to the rapid multiplication of these colossal water receptacles without adequate supervision or inspection. It may be argued that the interests of the corporation or company erecting the reservoir will be all on the side of making it as safe as possible, as its bursting would mean ruinous expense to them. But this notion of what constitutes safety may not always fit in with that of the public at large; and, in the event of a catastrophe, the latter would be infinitely the greater sufferer.

It may be worth while, therefore, to ask with what precautions the Legislature has hedged the security of reservoirs. The record of these precautions must be something akin to the historic chapter on 'Snakes in Iceland': there are none. It is true that under sections 5 to 11 of the Waterworks Clauses Act, 1863, anyone frightened at the danger of a reservoir may complain to two justices, who are to make inquiry into the truth of

the complaint. If it is found to be valid, and the danger is so imminent as not to admit of delay, the justices may order such person as they think fit to enter on the property of the undertakers and to do what is necessary. Or they may order the undertakers to take the necessary precautions, and in default get the work done themselves. This is all very well in theory, but is of no use in practice. What is wanted is some sort of guarantee that a reservoir shall be properly and substantially constructed in the first instance, and that it shall be kept in proper repair during its use. And to secure this there is no more workable or efficient plan available than inquiry and inspection by a Government or county official independent of the undertaking.

Some day, when a great catastrophe has happened through the bursting of one of those colossal reservoirs that have recently excited Mr. Ruskin's wrath, and that certainly do not add to the picturesqueness of landscapes whatever they may do to the comfort of townspeople; we shall have a fine clamour set up throughout the country, and a demand for a general inquiry or select committee into the subject. The diligent student may usually find by a little research in the attractive region of blue-books, that a Select Committee or Royal Commission has in days gone by made an exhaustive investigation into any given subject that may be named, and has issued, to quote a recent and sportive commentator, 'an elaborate report which nobody reads, full of the most excellent recommendations that are never carried out.' Of such is the question of reservoirs.

Well nigh twenty years ago a Select Committee, shocked at the inundations at Holmfirth, took evidence as to the security of reservoirs, and reported their opinion that in all cases in which it was proposed to construct a large reservoir, the undertakers should submit to the proper Government department plans and sections of the site, and of the works to be erected, and also descriptions of the mode of construction; that a competent person should in all cases be sent to the site to verify such plans, and to inspect and report on the works that were to be constructed, so that if there were any glaring deviation from the rules laid down by any private or general Act respecting waterworks, the deviation might be made known to the central authority. The Select Committee further recommended that when any reservoir was completed, the undertakers should be bound to give due notice of such completion, and that such reservoir should not be filled with water until after the expiration of a specified time. They suggested moreover that an adequate supervision over all large reservoirs should be maintained by the central authority; and to that end, from time to time, competent persons should be sent to inspect and report upon such reservoirs. Sound recommendations these; but they have met the fate of many others as good in having been persistently ignored for twenty years.

DR. SWEET, medical officer of the Hebburn-on-Tyne Local Board, reported at their last monthly meeting that the births in the district during the month of November show an average of 42.9 in the thousand, whilst the death-rate during the same period was only at the average of 12.5 per thousand per annum. These returns are not less satisfactory than remarkable, considering the great distress that exists in the district from want of employment.

PAYMENT BY PATIENTS IN HOSPITALS PROVIDED BY LOCAL AUTHORITIES.

THE Public Health Act, 1875, by sect. 131, enables local authorities to provide, for the use of the inhabitants of their districts, hospitals or temporary places for the reception of the sick; and for that purpose to themselves build such hospitals or contract for the use of any hospital already existing. The expenses of maintaining in such hospital a patient who is not a pauper are, by sect. 132, to be deemed to be a debt from the patient to the local authority. There is no general power to compel patients to go into hospitals; but where there is a hospital in or near the district of a local authority (whether provided by that authority or not), any person who is suffering from a *dangerous infectious disorder, and is without proper lodging or accommodation, &c.*, may, on the certificate of a legally qualified medical practitioner by order of a justice, be removed to such hospital at the cost of the local authority (sect. 127). [The question of the fitness of the lodging or accommodation of the patient must be decided with reference to the possibility of keeping other persons free from infection, as well as to the suitability of the lodging for the treatment of the patient.] If he is properly removed to a hospital provided by a local authority, such authority have the same power of recovering the cost of his maintenance there as if he had voluntarily become a patient; but, unless care is taken, they may find themselves unable to enforce their charge.

The cost of maintaining an individual patient in a hospital is not generally very great, and, consequently, where the payment is disputed, such cases are not likely to be brought into the superior courts. There have, however, been some cases in county courts which exemplify the difficulties with which local authorities have to contend. In the year 1881, Sir R. Harrington decided in the Warwick County Court that, though the expenses of maintenance in a hospital were recoverable from the patient, they were not recoverable from the person bound by law to maintain the patient (unless, of course, he has agreed to pay them), and consequently, that a father could not be made liable for the maintenance of his infant child in a hospital provided by a local authority. The SANITARY RECORD for November also contains a notice of a similar decision in the Salford County Court. A case decided on Nov. 4 last by Mr. Metcalfe, Q.C., at Bristol, goes still further. In that case the patient, a child, was admitted to the Bristol Royal Infirmary, and, when there, was discovered to be suffering from typhus fever. The Royal Infirmary, apparently, is not intended for the treatment of infectious cases, for the medical officer tried to send the child to the fever hospital. That, however, was closed temporarily, in anticipation of an outbreak of cholera, and the child could not be admitted. Finally she was taken into the infectious ward of the Stapleton Workhouse Infirmary, and was there treated successfully, and after five weeks discharged cured. The guardians of the Stapleton Union tried to recover the cost of her maintenance during the above period, but her father resisted payment on the ground that he had not consented to his child being removed to the workhouse infirmary, and would have preferred to have her nursed at home. He had other children at home, who would have been exposed to the infection, and it was evident that the case was a most proper one to be treated, as it

was, in an infirmary set apart for infectious cases. There had, however, been no magistrate's order for the child's removal, and on that ground (apart from the question of the father's liability to pay for her at all), the judge was obliged to decide against the claim.

It certainly seems as if the law might, with advantage, be amended so as to secure payment of the expenses incurred in treating patients whose families are in a position to afford it. It is, however, both the moral and the legal duty of local authorities to take steps to secure the proper treatment and isolation of all infectious cases, as far as possible; and even where they fail in recovering the cost of maintaining such patients in their hospitals, they and the ratepayers may consider such money as well expended, if it secures the removal of a patient who might have become a source of infection to the neighbourhood.

THE NUISANCE CAUSED BY RAILWAY-WHISTLES.

WE recently called attention to the rights and liabilities of those persons who choose to keep animals which annoy the neighbourhood by the noise they make. Letters have since then appeared in the *Standard* complaining of the much more serious annoyance produced by the constant shrieking of railway-whistles on the suburban lines. It has been asserted that a crowing cock or a barking dog is a nuisance injurious to health, on the ground that it may deprive an invalid of necessary rest; and there can be no doubt that the same remark applies to railway-whistles. The objection to the animals applies, however, with much more force to the whistle, because it is so much louder and more penetrating, and consequently can exercise so much greater a disturbing influence.

Both in common estimation, and also by English law, any loud and continuous noise which interferes with business or with the enjoyments of life, is a nuisance; and if such a nuisance is caused by any person who has no right to cause it, an action may successfully be maintained against him in respect of it. For instance, there is a case on record where such an action was successfully brought to abate the nuisance caused by ringing church bells; but such actions would generally fail on the ground that there was a prescriptive right to ring the bells, and consequently that the person aggrieved would have no right to complain. It is generally supposed that the railway companies have a right to blow their whistles, and consequently that those persons who are annoyed or injured by the practice have no remedy. The companies obtained the land on which their lines are constructed under Parliamentary powers, for the purpose of using them as railways; and it has long been settled law that no one has a right of action against them merely because, from the proper exercise of their Parliamentary powers, he has sustained damage. In an old case of 'The King against Pease' it was held that, though the engines on a railway by frightening the horses on an adjoining highway caused what is regarded by our law as a nuisance, still that nuisance was authorised by the statute under which the railway was constructed, and consequently that the company was not liable. This exception, however, extends only to the proper and careful doing of the acts so authorised, and in a subsequent case an action was suc-

cessfully brought against a company to recover damages consequent on an engine-driver suddenly letting off steam close to a place where the line crossed a road, and so causing a horse to take fright. We believe that there have also been cases where the companies have had to pay damages for frightening horses by whistling, but we cannot find them reported.

If persons with statutory powers improperly exercise them in such a way as to cause not merely temporary injury to individuals, but a continuing nuisance to them, or still more to a neighbourhood, the Courts will not merely give damages to the persons aggrieved, but will grant injunctions prohibiting the continuance of the nuisance. The cases in which this has been done are not at present very numerous; but the principle on which such injunctions may be granted was much discussed, and may be taken as having been now settled by the judgments of the House of Lords in the Hampstead Hospital case. If the action of the body purporting to act under Parliamentary powers causes a nuisance, it is not justified, unless it is apparent that those powers could not be exercised otherwise. No one can pretend that the constant sounding of a railway-whistle is necessary for the purpose of conducting the traffic. Trains might run, and in many places do run, without the whistle being used at all. In America the engines carry a large bell, which is used for the purpose of warning the signalmen and the public that a train is coming; the whistle is reserved for the purpose of frightening stray cattle off the rails and other similar emergencies. In populous districts in our Country the use of the whistle might well be prohibited. If persons aggrieved would combine to bring a test action against one of the offending companies, an injunction would probably be obtained, and the nuisance abated. There are two recent instances where such a course has been successfully adopted for the suppression of nuisances caused by railways near London. Several actions were brought against the Great Northern Railway in respect of the nuisance and injury caused by their coal yard at Islington. In some of these the plaintiffs failed to show that they personally were damaged, and consequently they lost; but in one case, at least, the plaintiff proved a substantial nuisance, and obtained an injunction, prohibiting the company from so conducting their coal yard as to cause a nuisance for the future. The other instance was that of an action brought to restrain the London Brighton and South Coast Railway from continuing a nuisance, caused by the noise connected with their cattle yard at Croydon. It was proved that the bulk of the nuisance was caused by drovers in driving cattle to and from the yard—for which the company were not responsible—but yet an injunction was granted. In both the above instances the defence of the company was that any injury sustained by the plaintiffs was caused by the exercise of their statutory powers, and that consequently they were protected, and in both instances that defence failed. We have no doubt that it would fail also as regards whistles wherever a strong case of injury and nuisance was proved.

The Corporation of Newcastle have made an application to the Local Government Board for leave to borrow 16,000*l.* for the erection of a new hospital for the treatment of infectious diseases, and 7,000*l.* for the erection of a refuse destructor for that city.

NOTES OF THE MONTH.

OPEN SPACES.

Those who are interested in the question of providing additional open spaces in the crowded parts of London, the second annual report of the Metropolitan Public Garden, Boulevard, and Playground Association (83 Lancaster Gate, W.) will prove valuable. The pamphlet, just issued, reveals fully the useful objects of the Association, but also several channels into which the energy of Lord Brabazon and his associates has been directed during the past twelve months. Of the seventy-eight matters taken in hand thirty have been successfully carried through, a result which represents all amount of hard work. Amongst these successful undertakings is the conversion of part of the disused site of the old Horsemonger Lane Gaol, Stepney Causeway, into a splendid public playground for boys and girls, daily used by about 2,000 poorest children, and where perfect order is maintained by two caretakers. Valuable assistance has been given towards the formation of public playgrounds and gymnasias in Stepney, Mile End New, Newington, and Bermondsey. The London County Council Board has been urged to extend the use of school playgrounds, and, with the aid of the Association, has appointed a Swedish instructor of gymnastics and a special committee to attend to the physical training of the children. The Duke of Devonshire has kindly allowed the Association to open and maintain the garden of Ebury, Pimlico—a step immensely appreciated in the neighbourhood; and the Marquis of Northampton has done the same with regard to Canonbury, which has been rendered very attractive in so doing. The great advantage of opening to the public similar enclosures. Seats have been placed in the disused burial-grounds of St. Dunstan, Stepney (where the Association has also provided a caretaker), St. James, St. Mary, Lambeth, and through its other burial-grounds have been beautified and made open, including Bunhill Fields and St. George's, Hanover Square; while to it are also due the opening out and opening by the Corporation of small gardens at the south-eastern end of the Priory Bridge, the placing of seats in the Royal Albert, Chelsea, and other works for the public. The Association assisted in opposing the Metropolitan Railway Bill and the appropriation for rail-ways of a part of Barnes Common; it helped to defeat Mr. Hollond's 'Disused Burial-grounds Bill' and saved from the builders' hands the disused burial-grounds of Peel Grove, Bethnal Green, the Bones, Borough, Guy's Hospital, and Christ Church, Westminster.

The report includes the Metropolitan Open Spaces Act (1881), the Disused Burial-grounds Bill, and a memorandum of steps to be taken in converting churchyards into gardens, besides three tables and unique lists, one with particulars of Metropolitan burial-grounds, compiled by Miss Gladstone, and two, compiled by Captain Pearson (Secretary), containing details regarding 34 existing open spaces, with remarks upon access from those who live in their neighbour-

The pamphlet ends with a long list of memoranda including many of the leading philanthropists of the day and a large number of the London clergy.

The work, so ably done in the past, is most encouraging, but to continue it an increase in the number of subscribers is much needed. We do not look without hope upon the unsuccessful work of the Association, knowing that, although the desired results may not be immediately attained, public attention has been drawn to the several matters, which must in time produce good fruit.

POISONING BY TINNED FOODS.

POISONING by tinned foods has of late been by no means an infrequent occurrence, and Dr. Nicholas records in a recent report on the health of Wandsworth that many complaints (reasonable foundations for which have been within his own knowledge) have been made of serious illness having resulted from the use of these provisions. Dr. Nicholas believes that, in many instances, the cause of such illness arose from the decomposition which some of such foods undergo from lapse of time. It seems to have been assumed, alike by vendors and purchasers, that these viands, having been hermetically sealed after the exclusion of air, undergo no change for an indefinite length of time. Dr. Nicholas points out, however, that the exhaustion of the air contemplated by the process employed in the manufacture, is not, and indeed cannot, be complete, and the decomposition, however much delayed, must surely and gradually take place. As it is impossible for the purchaser of these foods to determine how long they have been prepared, Dr. Nicholas suggests that some guarantee of their age should be afforded by the stamping of the tins with the date of manufacture, either through the agency of the Board of Trade, or some other Governmental procedure.

This suggestion does not at first sight appear a very promising one; but we think that the whole question of tinned foods—their importation, their constituents, and their influence on health—might profitably receive the attention of the Local Government Board.

CHEAP PUBLIC BATHS.

A FEW months ago Lord Brabazon made an able and eloquent appeal for the provision of public baths and washhouses (*see* SANITARY RECORD, Vol. xv., p. 432), in which he emphasised the duty of providing and maintaining these places as one coming properly within the jurisdiction of local authorities. Lord Brabazon may perhaps take courage from the following notable illustration of the successful inauguration and working of public baths erected by a municipality, as reported by Mr. Francis Vacher in a recent report on the health of Birkenhead. The building is of red brick, and occupies a fairly central situation as regards the whole borough. The accommodation provided consists of a large plunge bath, 47 feet by 32 feet, with 22 dressing boxes, a children's plunge bath, 12 feet by 9 feet, with dressing boxes, and 10 private baths in separate compartments—one male and one female first-class, five male and three female second-class. The children's plunge bath is often available for women, and the large plunge bath is reserved for women on Wednesdays from 6 A.M. to 2 P.M. During the summer months the establishment was kept open from 6 A.M. to 9 P.M., and during the winter months from 8 A.M. to 7 P.M. The charge is from 6d. to 3d. for the large plunge bath, from 1s. to 6d. for the small plunge

bath, 1s. for a first-class private bath, and 6d. for a second-class private bath. The money taken from March 1 to Dec. 31 amounted to 589*l*. In the week ending August 26 the amount taken was highest, being 27*l*., whilst the lowest amount taken (2*l*. 9s. 2d.) was in the week ending Dec. 16. The total sum of the baths given was 29,354. The large plunge bath was by far the most patronised, the number of bathers being 23,990, of whom 327 were females. The staff employed consists of a superintendent and matron, at a salary of 100*l*. a year, an engineer at 30*s*. a week, a bath attendant at 17*s*. a week, a charwoman at 15*s*. a week, and during the summer months a washerwoman at 15*s*. a week. The success of the baths during the first year of their existence exceeded the most sanguine expectations of the Council, and their provision proved a rival attraction to the public bowling and quoiting ground in Birkenhead Park. Local authorities possess ample powers for the establishment and maintenance of baths of this description, and it is greatly to be wished that these powers were much more generally availed of.

THE WORKING OF THE ALKALI ACTS.

THE annual reports to Parliament on the working of the Alkali Acts will no longer be illuminated by the quick intelligence and scientific insight of the late lamented Angus Smith. His methods of work might not be strictly official, nor his language quite so polished as that of the accomplished compilers of the annual Blue-books of the Local Government Board itself; but his reports breathed the true spirit of inquiring vigilance, and of the enjoyment of work undertaken more as a labour of love than anything else. The last official product of his pen has recently been published as a Parliamentary paper, and possesses from this circumstance additional, though a somewhat pathetic, interest. It records, what must have been to its compiler a source of genuine pleasure, the steady growth of the principles upon which the Alkali Acts were framed. The total number of alkali and other works in the United Kingdom at the end of 1883 was 990, of which 802 were in England, 140 in Scotland, and 48 in Ireland. Of these, no less than 49 were registered for the first time during the year. The great majority of the new works were for the manufacture of chemical manure and sulphate of ammonia, the increase in the number of the latter works being due to the fact that the owners of the smaller gasworks have discovered that they can more profitably manufacture and sell their sulphate of ammonia than send the bulky gas-liquor to a distance. To this discovery, also, the increased profits which have been made of late years by the carrying on of gas undertakings are no doubt to some extent due; for the manufacture of residuals, when judiciously managed, has in many cases of late years proved scarcely less profitable than the manufacture of the gas itself. In many of the new works, oxide of iron purifiers have been erected as the best means of preventing a nuisance from sulphuretted hydrogen; and in some works this gas is now completely burnt, instead of being allowed, as formerly, to escape unburnt up the chimney into the atmosphere. At one work, Claus' method of dealing with sulphuretted hydrogen by burning it has been introduced, so as to form sulphur, which is collected. The extent to which oxide of iron purifiers are being adopted throughout the country may be gathered from the fact that in one district only they were

introduced into twenty-three works in 1883. Special attention was devoted to alterations and improvements in the treatment of the sulphuretted hydrogen evolved in the manufacture of sulphate of ammonia, and in the washing of the gases emitted in the treatment of coprolites and other materials with sulphuric acid at chemical manure works. As regards alkali works proper, the chief improvement has been effected at Newcastle, where, in six works, the pan outlets have been done away with, and connections made with the chimneys, the suspicion of escape being thus reduced, and the inspector enabled to do his work of testing more speedily. Only one work at Newcastle has now pan outlets.

FORTHCOMING EXHIBITIONS.

IT is an assured fact that we are living in an age of exhibitions, and the great success which has attended those combining amusement with instruction held during the last two seasons at South Kensington, appears likely to promote their extension to provincial centres as well as throughout the metropolitan area. In addition to the Exhibition of Inventions in relation to science and the art of music at South Kensington, an 'International' Exhibition at the Alexandra Palace, Muswell Hill, is promised. Everything that can be consistently offered to exhibitors to induce them to patronise the exhibition at Muswell Hill is offered, including five classes of awards, in which a diploma of honour is the highest prize, gold medals figuring as second awards, while low fares by railway and entrance fees, based on the most liberal tariff, are set forth to attract the public, who are promised amusements and entertainments of the most varied character. The Exhibition is to commence on March 31 next, and to remain open for six months, and the building and grounds will be illuminated by the electric light. One of the most laudable features in the arrangements is that 10 per cent. of the gross receipts from admission money is to be set apart for distribution amongst the principal London hospitals. For this purpose a committee has been formed, including Colonel Sir Herbert Sandford, R.A., as chairman, Admiral Sir Edward Inglefield, C.B., vice-chairman, and General Sir Michael Kennedy, K.C.S.I., Sir Henry Pitman, M.D., Sir Andrew Clark, Bart, M.D., F. D. Dixon Hartland, Esq., M.P., and George Johnson, Esq., M.D., as members of the executive. The bankers to the fund are Messrs. Coutts & Co., the executive commissioner Geo. Collins Levy, Esq., C.M.G., and the secretary Edgar Ray, Esq., the City offices being at 19 & 21 Queen Victoria Street, E.C.

Our American kinsmen have also determined to hold an exhibition in London in 1886 of American manufactures and products only. It is intended to be of a most comprehensive character, and has received the hearty support of the governors of the different States and presidents of the principal railway companies, as well as of representative men in all branches of manufacture and produce. This interesting show will be truly national in character, and in it the English public are promised the opportunity of seeing American artisans (both white and coloured) at work in various handicrafts. For many months past General C. B. Norton, the secretary, has been located at the administrative offices, No. 7 Poultry, E.C., organising the movement. General Norton is no novice in the business.

having been engaged in connection with American exhibitions since that of Paris in 1867, in which he was a commissioner from the United States. The locality where this exhibition will be held is not yet fixed; and if an appropriate building cannot be obtained, a special one will be erected for the purpose. If there is anything to be learned from the modes of procedure in the different American industries, our manufacturers and artisans will thus have an opportunity of profiting by an inspection of them without trouble or outlay—no mean advantages in these times of keen industrial competition. There is also little doubt that London generally will greatly benefit in a pecuniary as well as cosmopolitan point of view from the ingress of Transatlantic visitors.

THE NATIONAL HEALTH SOCIETY.

THE National Health Society is now a corporate body. This step was felt to be a wise one, owing to the fact that the Society has done, and is doing, work of so much use and importance to the public; and therefore an Act of incorporation has been secured. The Council of the International Health Exhibition has awarded to the Society a diploma of honour, and the members have memorialised the Prince of Wales, asking for a grant of money from the surplus funds. Dr. J. J. Pope is lecturing for the National Health Society in Leek, Bedford, and other provincial towns, and several gentlemen of experience have undertaken, during the winter, to give simple instructions to audiences of working men and lads in the East End as to what to do in cases of injury and accident. Dr. Roberts is lecturing in the district of Keighley under the Society's auspices, and a course of drawing-room lectures, especially intended for ladies, is to commence shortly in the west of London. The Sub-committee on Poisonous Dyes has resumed its useful work. The members of the Society have passed a resolution expressing their regret at the proposed destruction of the Sanitary and Insanitary Houses, lately exhibited at the Health Exhibition, and requesting the Committee to consider if it would not be possible to remove them to some position where they could again prove of interest and use to the public.

THE ADVANTAGES OF HOSPITAL ISOLATION.

ONE of the most encouraging evidences of sanitary progress is the increasing provision which is being made by local sanitary authorities in various parts of the country of infectious hospitals for the isolation of cases of infectious disease, and the growing appreciation on the part of the public of the benefits of such hospitals. When inquiring, some time ago on behalf of the Local Government Board, into the whole question of isolation provision and administration, Dr. Thorne Thorne found that, with but few exceptions, these hospitals had been used for the treatment of infected people who, in the absence of any provision of the kind, could not have been isolated at all, and must, therefore, have spread disease to their neighbours. Since the publication of that report some forty or fifty hospitals have been erected in various parts of the country; and the instances recently recorded in these columns leave no doubt as to the favourable change that is taking place in the attitude of public feeling towards them. Of the usefulness of individual infectious hospitals, the past

year has afforded some noteworthy examples. Thus at Ipswich, where the resources of the hospital were severely taxed by an outbreak of small-pox and an extensive prevalence of scarlatina, a total of 85 patients were treated with but one death, the remaining 84 being discharged cured. Since the opening of the hospital in Aug. 1881, the mortality amongst the inmates has been remarkably low, four deaths only having occurred amongst 180 patients. This experience, which is not uncommon, demonstrates the increased chance of recovery which a sufferer possesses when treated in clean and airy wards, attended by trained nurses, and receiving the benefit of skilled medical attendance. It would not be difficult to imagine what would have happened had these 85 people been treated at their own homes, for at Leicester, where the treatment of cases of scarlet fever at home exercises a more or less paralysing influence on the efforts of the local authorities, as many as 797 houses were attacked by scarlet fever in 1883. Dr. Johnston's experience then has proved beyond doubt that when this disease once gains admission into artisan dwellings, it is quite exceptional for any of the younger members of the families to escape it. The patients admitted into the Leicester hospital suffering from this disorder numbered 383, and of these 25 proved fatal; whilst amongst the cases treated at home (estimated at 414) there were 66 deaths. The Birkby Hospital, at Huddersfield, proved, too, of the greatest service in effecting isolation. Here 75 cases were admitted, the majority of admissions being from scarlatina and typhoid fever. The deaths included two from each of these diseases, one from diphtheria and one from tuberculosis. One hundred and twenty-nine patients were received into the Warrington Hospital, and of these 104 were discharged cured, 12 died, and 13 remained under treatment at the end of the year. At Gateshead the Borough Hospital was found most valuable for the isolation of cases of the more dangerous infectious disease. Mr. Green, the medical officer, found that when cases were reported and removed early in the disease, it was extremely rare that other members of the household or neighbourhood suffered. But when cases could not be removed, other cases almost always occurred, and the disease spread. Of the 233 cases admitted for treatment, of whom no fewer than 177 were suffering from small-pox and 46 from typhus fever, 44 proved fatal, or 18·8 per cent. Dr. Bryden Hill, the health officer of Oldham, estimates that as compared with the average of the years 1872-81, there was a saving in 1883 of 333 lives from infectious disorders alone, and he attributes no small part of this to the existence of a fever hospital and the compulsory notification of zymotic disease. We could multiply instances of this kind from the interesting and valuable reports of health officers which are sent to us in such embarrassing profusion; but it is scarcely necessary. The value and utility of infectious hospitals is beyond question; and we are happy to think that the prejudice which formerly existed against their use is rapidly dying out.

THE SMOKE NUISANCE.

AT the present time of the year, when fog-producing causes bring all their influence to bear, it behoves every individual to exert his utmost to restrain every agency for evil in this respect, and it is satisfactory

to note that the authorities are keeping an ever-watchful eye upon offenders, casual or otherwise. The proprietor of a sugar refinery in Spitalfields was summoned during the past month, under the Smoke Nuisance Act, for using one of his furnaces not so constructed as to consume the smoke, and it was proved that very frequently the neighbourhood of Spitalfields was clouded by the dense volumes of smoke which issued from the defendant's works, the dates and times being given at which the nuisance was observed. The magistrate said that complaints had been made continually since July last, and the defendant had been before the court more than once, so that he really appeared to be a frequent offender. Under the Act a double penalty was to be imposed for each successive offence, and the recalcitrant and impenitent 'refiner' was therefore fined a sum of 20*l.*, and ordered to pay in addition costs amounting to 1*l.* 13*s.* 6*d.* According to the Report of the Council of the National Smoke Abatement Institution recently issued, it is stated that the past year may be considered to be the first year in which the movement has worked in an organised manner, and has had the opportunity of indicating and developing its practical utility, and if the foregoing instance may be taken as an example of its procedure, there can be no doubt as to the efficiency of the members, and of the results which, as might be expected, are making good headway. Owing to well-applied efforts, both in London and the provinces, other successful action has been taken, and local authorities are diligently carrying out their powers. The efficacy and economy of gas-engines are becoming generally known, and these cleanly and active machines have increased in number very rapidly during the past three years. The total number now at work in London is estimated at upwards of 6,000, and thus a considerable quantity of smoke has been prevented by their use. Referring again to the Report, it was stated by the traders' deputation who recently waited upon the Council, that for fuel gas is generally more expensive than coal at present prices, and therefore the deputation begged that the Council would represent the case to the gas companies of the metropolis, and invite the directors to consider whether a reduction in the price of gas supplied for *trade* purposes could not be made, the quantity of gas now used being very considerable, and likely to be largely increased by a reduction in the price. The competition of electric lighting having awakened the gas companies to a sense of their position, it is more than likely that a suggestion of this kind will obtain the hearing and attention that it deserves. The improvements in domestic grates, and the extension of heating by hot water, are too well known to be recapitulated; but it may be useful to remind householders that the newer forms of stoves are fully 20 per cent. superior in efficiency and economy to those of even three years past. Legislation, however, is hardly keeping step with the increase of knowledge and interest which are brought to bear upon the subject, and in London it is necessary that the area now covered by the Smoke Abatement Act should be extended, that all the trades which do not at present come within the operation of the Acts should be included, as should also be domestic dwellings which are much to blame; and further that the smoke of steamers on the river, which is now enormous, and practically unchecked, should be brought under control, and the smoke from the locomotive engines on the railways throughout the

metropolis should also be restrained. They are not alone in hoping that these changes will receive the immediate attention of the Legislature.

THE BOUNDARY COMMISSION

THE Government is sanguine if it imagine Boundary Commission, even with the sphere of operations described by Sir Charles Dilke is likely to accomplish its labours in any of the two months that is allotted to it. It is a substantial portion of the work has already done whilst the Redistribution Bill was embryo, but a great mass of cutting and will nevertheless have to be got through new constituencies can be pieced together however, is a matter in which we have interest beyond that felt by most people of prizes; but what does concern nearly is the disheartening nature of the suggestion to Mr. Borsari's excellent practical suggestion to assign to the Commissioners the function of mapping districts for the purposes of local sanitation, as well as for political representation, the memory fresh upon us of the tantalising of local government reform with which the Local Government Board dined at the House at the beginning of last year must refuse to believe that Sir Charles Dilke's duties as Chairman of the Commissioners' duties was by anything more than a very natural to keep the redistribution arrangements as possible from disturbing or delaying. His sympathies with a reform of consolidation of areas are too pronounced to turn an absolutely deaf ear to Mr. Goschen's dictum concerning it. The mess of the subject will not, however, present chaos of jurisdiction among local authorities. By all means let the Boundary Commissioners through their work with what celerity they let them not afterwards be disbanded experience, and the copious materials at hand, have been utilised in framing a scheme for the redistribution of areas for the purposes of local self-government.

THE SALE OF HORSEFLESH AS FOOD IN BIRMINGHAM.

CONSIDERABLE commotion has been caused by the meat-eating population of Birmingham seizure of a large quantity of horseflesh premises of a butcher in the central part of the town, such flesh being so unwholesome as to be promptly condemned and destroyed. The consternation was not lessened by the fact that the flesh was evidently intended for sale as human food either in the shape of joints, boned meats, or pies. It appears that the suspicions of the officials had been aroused to the fact that in horseflesh was going on between Birmingham, Liverpool, and Manchester, in the latter places the Corporation had some by-laws in consideration, one of which it is understood forbade horseflesh in a sound state to be sold as food if it be legibly labelled as what it is. On Nov. 22, an inspector of nuisances, William Latham, visited one of the salaried

saw a hamper, fastened with copper wire, and a most offensive odour proceeded. A man attached to the hamper bearing the address of Mr. Arthur Leeson, Lawley Street, Birmingham, was left till called for. Carriage paid.

The inspector watched the hamper and a barrel accompanied it for some hours, at the expiration of which he saw a man drive to the station and take the hamper and barrel. The officer followed the packages to a shop situated No. 74, High Street, Birmingham, which had written over the door 'Beef and Mutton Company.' Having seen the support of another officer, Latham went into the shop and questioned the man who had fetched the packages to the station as to the contents. Ignorance was expressed on this subject, but eventually the packages were opened. The hamper contained pieces of raw horseflesh in a wet condition, and on appearance as though the animal had died from inflammation and died. In the barrel were three pieces of horseflesh in brine. The packages afterwards seen by the veterinary inspector, borough medical officer, and condemned for food. Other empty packages of a kind were found on the premises, but no more horseflesh. On Tuesday, the 2nd inst., the owner of the premises, Richard Pearson, a butcher, was summoned to the Birmingham Police Court, before Mr. Kynnersley, stipendiary magistrate, to answer a charge of selling his premises thirty-five pieces of horseflesh for sale as food, and unfit for human consumption. Evidence was given to the above effect. It was stated that the horseflesh was boned, and Latham said that although it was not known where the pieces were made on the defendant's premises, the horseflesh in the course of being manufactured into sausages in the town. It was sought in cross-examination that the flesh might have been intended for cats and dogs; but the defence insisted that in that case it would not have been brined. For the defence it was contended that the hamper and barrel were consigned to the defendant's son-in-law, that the defendant had no guilty knowledge of the contents of the packages, which he had not even opened when the officers entered the shop, and that it had not been proved that the defendant intended offering the packages for sale. The result was that the stipendiary magistrate dismissed the summons. On another occasion it was well that the officers should not allow their discretion in matters of this kind to be overruled, that their proof is sufficient to bring the affair to a crisis. Since the case was written, it has been determined by the Court to appeal against the stipendiary's

refused to pay the rates demanded. That decision has since been followed by other judges, and it seems that the ratepayer must at any rate take steps to bring his dispute before two justices, the proper tribunal for deciding it, and cannot content himself with refusing to pay more than he considers the proper valuation. If he does, he may find himself and his dependents left without any supply at all. The prudent course is to pay *under protest*, and proceed as soon as may be to have the assessment settled by justices. This may entail trouble and some expense (though, if the reduction claimed is obtained, the justices generally allow costs), but no other course is safe.

Actions have recently come on for trial in different county courts in which consumers, who have succeeded in getting their assessments reduced, have tried to recover back the moneys which they had overpaid before the reduction. Such moneys were paid under the mistaken belief that they were legally due at the time they were paid, and ordinarily money paid under a mistake of law cannot be recovered. As far as we have seen the decisions have all been given in accordance with this principle, against the claimants and in favour of the companies. The question will probably in time be brought before the High Court by way of appeal. It is never safe to prophesy; but unless there should be some special circumstances to alter the matter, we anticipate that these decisions will be upheld, and that ratepayers who have now got their rates reduced must be satisfied without getting back any money which they paid in the past. This does not of course apply to money paid under protest while disputes are pending, in order to avoid a distress or the supply being cut off; such money was held by Mr. Chalmers, the County Court Judge of Birmingham (in the case of *Smith v. The Corporation of Birmingham* decided by him Dec. 5, 1884), to be recoverable, while overpayments made previously without protest were not recoverable.

THE LOCAL GOVERNMENT OF LONDON.

THE Council of the London Municipal Reform League have buoyant spirits. They have passed a resolution which in effect calls upon the Government to give early and sustained attention to the question of the Local Government of London, in order that a Bill settling the question once and for all may be passed in the next Session of Parliament. We have every sympathy with the objects of the League; but no great opinion of their political foresight or discretion. The hatching of the Redistribution Bill by the joint incubation of the leaders of the two parties appears to have lulled to sleep most of the apprehensions which were so freely expressed a month or so ago as to the political struggles of next Session. But have these good easy people reflected that something like a fourth of the whole House of Commons are invited to give themselves the happy despatch? Even supposing that the debates on the Redistribution Bill are less lengthy than there is reason to expect, with what spirit will a moribund Parliament, conscious that it only exists on sufferance until the equipment of the new electorate can be completed, take up a question so large and so embarrassing as the municipal reform of London? We yield to no one in dissatisfaction with the existing state of things and desire to see a better; but let us be reasonable in the matter. A Bill like the Home

WATER RATES.

Between water companies and their customers a contest will continue, and for the most part the contest will be brought forward as the same as which we have already commented. There are, however, two points which have recently come under our notice which deserve special attention. In our last month's number we noticed a case in which the High Court refused to grant an injunction to restrain a company from exercising its power of cutting off the supply, where the company, alleging the charges to be excessive,

Secretary's could only be safely piloted through the shoals and quicksands of the present Parliament by a sacrifice of a good deal of the cargo. In the next Parliament, the metropolis will be numerically and positively much better represented than at present. Let the electors of each of the fifty-seven new metropolitan constituencies make the municipal reform of London a test question for candidates. A solid phalanx of members pledged to such reform could carry through a comprehensive and statesmanlike measure in the first session of a new Parliament, whilst to attempt to force a solution of the question next year would inevitably mean a spineless, truncated and generally inefficient measure as an alternative to nothing at all.

SALE OF BREAD BY WEIGHT.

ENGLISH law does not as a rule interfere with the way in which a tradesman conducts his business. He is generally free to sell his goods in such shape, in such quantities, and of such quality as he thinks fit, and the customer is left to make his own bargain or abstain from purchasing if he does not like the tradesman's terms. There are, however, some exceptions in which, for the benefit of the community, Parliament has thought well to impose certain restrictions. For instance, dealers must have weights and measures of specific denominations, and are liable to heavy penalties if those weights and measures are inaccurate. So also, in case of drugs and articles of food and drink, the dealer is liable to penalties if he adulterates them, or if he sells them not being in nature and substance the articles demanded by the purchaser. The law as to adulteration does not, however, extend to all articles. A draper may sell a piece of cloth which contains little or no wool, or a cutler a knife whose blade is iron instead of steel, and unless he has warranted or fraudulently represented the article as being something which it is not, the law cannot interfere with him. The law also punishes dealers who sell articles of food which have become unsound or unwholesome, although not adulterated. In the case of bread the purchaser is further protected by provisions which oblige the dealer to sell by weight. These provisions are contained in an Act passed in the year 1836, 6 & 7 Wm. IV., c. 37, which repealed previous statutes imposing more severe restrictions. It allows bakers to sell bread in loaves of such weight and size as they like, but forbids the sale of bread otherwise than by weight, except such bread as is usually sold under the denomination of French or fancy bread or rolls. In order to carry out this requirement as to sale by weight, the Act also requires all bakers or other sellers of bread to provide in their shops proper scales and weights, &c., 'in order that all bread there sold may be from time to time weighed in the presence of the purchaser;' and also that every cart or carriage employed for delivering bread shall be constantly provided with scales and weights, &c., 'in order that all bread sold may from time to time be weighed in the presence of the purchaser.' The object of these sections is clearly that the purchaser may have an opportunity of seeing that he gets the weight he pays for, and of testing that in the presence of the dealer or his agent, so that incorrect weights may be detected and put right at once. It is not necessary to weigh every loaf in the presence of the customer, but the baker is liable to a penalty if he sells anything but

the full weight, and is bound to provide scales for weighing, and to weigh the loaves when required. The provision as to carrying scales in carts is one which bakers apparently neglect and wish to get out of, for on two occasions at any rate they have thought it worth while to dispute it as far as appealing to the High Court, each time unsuccessfully. In the year 1875, in the case of *Robinson v. Cliff*, the point urged was that bread supplied under a general order given at the shop need not be weighed from the cart; and the other day, in the case of *Ridgway v. Ward*, the baker contended that where a loaf had been ordered and weighed (in the absence of the customer) in the shop, there was no necessity to have any scales in the cart. As these contentions failed, it may be taken as now settled that the law obliges bakers to carry scales and weigh bread at the time of delivery, if required. Bakers complain that this law acts unfairly on their trade, and say that they ought no more to be obliged to weigh bread at their customers' houses than a butcher is obliged there to weigh his meat. Perhaps the law might advantageously be altered by obliging the butcher and other tradesmen who sell goods by weight and measure to weigh or measure them on delivery, when required to do so by the purchaser. As far as we know, the only other traders who are now by law subject to any such obligation are coal-dealers in London, and, judging by newspaper reports, the scales they have to carry are sometimes the means of detecting very serious short deliveries. Any restrictions which make fraudulent malpractice difficult, which oblige the would-be dishonest tradesman to give his customer both the quality and quantity of goods he professes to sell, seem to us to be good. Honest men have no reason to complain of them, except in cases where they omit to observe them through carelessness. And carelessness, even where it is not culpable, deserves no special sympathy. We hope to see the law as to these matters made more stringent, rather than to see it relaxed.

HYGIENIC COMPARISON OF GAS AND ELECTRIC LIGHT.—It is stated in the *Centralblatt für Elektrotechnik* that experiments have been made at the Theatre Royal of Munich in order to determine the elevation of temperature and the amount of carbonic acid under illumination by gas and by the electric light. Before the play, at the time of the experiments, when there were no more than ten or fifteen persons in the building, the curtain was raised and all the lamps were allowed to burn for an hour. The temperature was observed, at intervals of five minutes, simultaneously in the parquet, in the balcony, and in the third gallery. During the plays, when there were on an average between 500 and 600 persons in the theatre, the thermometer was observed every ten minutes. The experiments showed that the electric light greatly diminished the increase of temperature. It does not render ventilation superfluous, but it requires a less active ventilation than gas, since it does not, like gas, contribute to the carbonic acid and to the increase of heat.

THE Dean and Chapter of Durham have offered a few acres of land on Gillesgate Moor to the Corporation of the city for the purpose of erecting a permanent hospital for the treatment of infectious disease; the only condition attached to the gift being that the proposed building should be erected at once. Small-pox is sensibly declining in the above city. Dr. Venn, the medical officer in charge of the temporary hospital for infectious diseases, reported at the last monthly meeting of the Council that there were only 49 cases in that building, mostly young persons.

THE PUBLIC HEALTH

DURING NOVEMBER 1884.

A temperature during the month of November at Observatory, Greenwich, was $42^{\circ}4$; it slightly the average November temperature in one ears, but was below that recorded in the corresponding month of any year since 1879. An excess of rain prevailed on thirteen days of the month, the other seventeen days it was below the average. The warmest day of the month was the 5th, when the mean was as high as $55^{\circ}5$, and $9^{\circ}9$ above the average; the coldest day was the 25th, when the mean was only $30^{\circ}7$, and $10^{\circ}2$ below the average. The rainfall measured at Greenwich on thirteen days of the month, to the aggregate amount of one inch, was less than half the average November rainfall in the last twenty years. During the first eleven months of this year the rainfall amounted to 15.5 inches, which was 0.8 inches below the average rainfall in the same month of the sixty-one years. The sun was above the horizon for 14 hours in November, but only 29.0 hours of sunshine were recorded at Greenwich; this amount is considerably below that registered in the corresponding period of any year on record. The direction of the wind was very variable throughout the month.

Twenty-eight large English towns dealt with by Registrar-General in his weekly returns, which have a total population of more than eight millions and six hundred and twenty-two thousand seven hundred and eighty-eight births and 14,580 deaths were recorded during the four weeks ending the 29th ult. The birth-rate, which had been 33.3, 34.4, and 34.9 per 1,000 in the three preceding months, declined again to 32.4 in November, but slightly exceeded the rate in the corresponding month of the preceding year.

In these twenty-eight towns the lowest birth-rate was 28.4 in Brighton, 28.5 in Plymouth, 28.6 in Bolton; in the other towns the rates ranged from 38.4 in Hull, 39.6 in Cardiff, and 40.2 in the birth-rate in London last month was equal to 1,000, while it averaged 34.8 in the twenty-eight towns.

The annual death-rate in the twenty-eight towns, declined from 24.2 to 20.5 per 1,000 in the corresponding months, rose again to 21.7 during the month of November. This rate, however, was below those recorded in the corresponding periods of the two preceding years, 1883, which were 22.4 and 22.6 per 1,000 respectively.

The lowest rate of mortality last month in the twenty-eight towns was 17.7 in Brighton. The rates in the other towns, ranged in order from the lowest, were as follows: Portsmouth, 19.2; Bristol, 19.4; Birkenhead, 19.9; Plymouth, 20.0; London, 20.3; Manchester, 20.7; Sheffield, 20.7; Blackburn, 20.7; Leicester, 21.1; Bradford, 21.9; Leeds, 22.1; Salford, 23.0; Oldham, 23.3; Halifax, 23.8; Hull, 24.0; Newcastle-upon-Tyne, 25.5; Wolverhampton, 25.5; Cardiff, 26.0; Nottingham, 26.4; Bolton, 27.8.

While the death-rate in London, as above stated, exceeded 20.3 per 1,000, it averaged 22.9 in the other provincial towns. The 14,580 deaths from the twenty-eight towns during the four weeks ending the 29th ult. included 1,547 which were referred to the zymotic diseases, of which 303 resulted from measles, 284 from scarlet fever, 200 from whooping-cough, 194 from diphtheria, 208 from diarrhoea, and 129 from small-pox. The death-rate was equal to 10.6 per cent. of the total deaths, and to an annual rate of 2.30 per 1,000. The rate showed a slight decline from that of the corresponding month, and was below those recorded in the corresponding periods of the two preceding years, which were 2.94 and 2.81 per 1,000 respectively. The death-rate in London during November

was 2.13 per 1,000; in the twenty-seven provincial towns it averaged 2.45, and ranged from 0.5 in Brighton, 0.5 in Plymouth, and 1.0 in Bristol, to 3.8 in Hull, 4.3 in Bolton, 5.1 in Preston, and 7.5 in Cardiff.

Scarlet fever was the most fatal zymotic disease in the twenty-eight towns during November. The rate of mortality from this disease in the twenty-eight towns, which had been 0.41 and 0.38 per 1,000 in the two preceding months, rose again to 0.45 during November, but was considerably below that recorded in the corresponding period of either of the two previous years, when it was 0.75 and 0.84 per 1,000 respectively. In London the death-rate from scarlet fever was 0.43 per 1,000, and slightly exceeded the average rate in the twenty-seven provincial towns, among which the highest rates were recorded in Salford, Sheffield, and Newcastle-upon-Tyne. The death-rate from measles, which had been 0.27 per 1,000 in each of the two previous months, rose last month to 0.42; in London the mortality from this disease was 0.31 per 1,000, while in the twenty-seven provincial towns it averaged 0.52, and showed the highest proportional fatality in Hull, Bolton, and Cardiff. The rate of mortality from whooping-cough, which had steadily declined from 1.10 to 0.30 per 1,000 in the seven preceding months, rose again during November to 0.37; this disease was almost twice as fatal in the provincial towns as in London, and was most prevalent in Leeds, Oldham, and Preston. The death-rate from 'fever' (principally enteric or typhoid), which had been 0.38 and 0.41 per 1,000 in the two previous months, declined last month to 0.35; the highest rates from this disease were recorded in Blackburn, Leeds, and Derby. The mortality from diarrhoeal diseases showed a further decline, and was below the average for the same periods of recent years. The death-rate from diphtheria corresponded with that in the preceding month; this disease was considerably more prevalent in London than in the provincial towns; 81 cases occurred in London, 16 in Liverpool, and 5 in Nottingham. During the four weeks of November 129 fatal cases of small-pox were recorded in the twenty-eight towns, showing a further considerable increase upon the numbers in the two preceding months; of these, 120 occurred in London, 4 in Birkenhead, 3 in Sunderland, 1 in Leeds, and 1 in Cardiff. Judged by the returns of the Metropolitan Asylum Hospitals, the prevalence of small-pox in London showed a marked increase during November. The number of small-pox patients under treatment in these hospitals, which had declined from 1,290 to 536 at the end of the four preceding months, rose again to 884 at the end of November. The average weekly number of new patients admitted to these hospitals, which had been 73 and 84 in the two previous months, rose during November to 203.

The rate of infant mortality in the twenty-eight towns, measured by the proportion of deaths under one year of age to births registered, was equal to 157 per 1,000 during November, against 156 and 162 in the corresponding periods of the two preceding years, 1882 and 1883. While the rate of infant mortality did not exceed 143 in London, it averaged 157 in the twenty-seven provincial towns, among which it ranged from 93 and 122 in Portsmouth and Derby, to 195 in Nottingham, 220 in Preston, 232 in Cardiff, and 245 in Bolton.

The death-rate from diseases of the respiratory organs, judged by the metropolitan returns, was considerably below the average during November. The weekly number of deaths referred to these diseases in London averaged 398, and the annual death-rate was equal to 5.2 per 1,000. In Liverpool the annual rate of mortality from these diseases was last month equal to 7.7 per 1,000.

The causes of 372 of the 14,580 deaths recorded in the twenty-eight towns during the four weeks of November were not certified, either by registered medical practitioners or by coroners. These uncertified deaths were equal to 2.55 per cent. of the total deaths, which exceeded the proportion in any recent month. In London the pro-

portion of uncertified deaths did not exceed 1·37 per cent., while it averaged 3·44 in the twenty-seven provincial towns, ranging from 0·0 in Plymouth, and 0·5 in Cardiff, to 5·8 in Halifax, 6·4 in Oldham, and 7·5 in Hull.

Among the population living in the outer ring of suburban districts around London, estimated at rather more than a million persons, the death-rate during November from all causes was equal to 18·5 per 1,000, against 17·7 and 17·8 in the corresponding periods of 1882 and 1883. During the four weeks ending the 29th ult., 59 fatal cases of small-pox, 41 of diphtheria, 20 of whooping-cough, 20 of measles, 16 of scarlet fever, 10 of 'fever,' and 9 of diarrhoea, were recorded in the outer ring. These 175 deaths were equal to an annual rate of 2·12 per 1,000, which slightly exceeded that recorded in the corresponding month of last year. The fatality of whooping-cough and of 'fever' declined, while that of each of the other zymotic diseases showed an increase. Of the 59 deaths from small-pox recorded in the outer ring during November, 54 occurred in West Ham district (including 20 of London residents recorded in the Metropolitan Asylum Hospital at Plaistow), 1 in Staines, 1 in Isleworth, 1 in Tottenham, 1 in Acton, and 1 in Willesden sub-districts. Of the 41 fatal cases of diphtheria 11 were registered in Kingston, and 7 in Edmonton districts.

NOTIFICATION OF INFECTIOUS DISEASES.

THE table on page 269 contains uniform statistics relating to sickness and mortality in thirty-one of the thirty-nine urban sanitary districts of England and Scotland in which the notification of infectious diseases is compulsory. The population of the thirty-one towns for which we are enabled to publish complete statistics for the month of November is estimated at about two-and-a-half millions of persons. The annual death-rate from all causes during that period in these thirty-one towns averaged 21·91 per 1,000 persons estimated to be living therein, showing a further decline from the rates recorded in the two preceding months, which had been 22·55 and 20·51 per 1,000 respectively. The rate of mortality in the twenty-eight large English towns dealt with by the Registrar-General in his weekly returns was 21·70 during November, and therefore was slightly below the rate in the thirty-one towns in the accompanying table. The death-rates last month were considerably below the average in Barrow-in-Furness, Hartlepool, Edinburgh, and Accrington; while they showed an excess in Nottingham, Warrington, Stalybridge, Preston, and Jarro. The death-rate from the eight infectious diseases dealt with in the table averaged 0·91 per 1,000 in the thirty-one towns, against 0·54, 0·77, and 0·98 per 1,000 in the three preceding months. No death from any of these infectious diseases was recorded last month in Lancaster, Leek, Macclesfield, Stalybridge, and Warrington; while in the other towns the rates ranged upwards to 2·00 in Bury, 2·03 in Hartlepool, 2·15 in Greenock, and 4·39 in Rotherham. Four deaths were referred to small-pox in Birkenhead; scarlet-fever was proportionally most fatal in Bury, Salford, Greenock, and Rotherham; enteric fever in Blackburn, Preston, Bury, and Derby; and diphtheria in Aberdeen, Burton-upon-Trent, and Greenock. Two deaths from typhus fever were recorded in Bury. With regard to the notified cases of infectious diseases in these thirty-one towns, it appears that the proportion to the population of persons reported to be suffering from one or other of the eight diseases specified in the table was 6·71 per 1,000, against 6·85 and 7·92 in the two preceding months. While the proportion did not exceed 0·94 in Warrington, 1·67 in Huddersfield, and 1·95 in Macclesfield, it ranged upwards to 10·00 in Salford, 11·49 in Hartlepool, 11·53 in Derby, 12·28 in Edinburgh, 12·41 in Barrow-in-Furness, and 18·65 in Rotherham. The excessive rate recorded in the three last-mentioned towns was due to the epidemic

prevalence of scarlet-fever. Thirty cases of small-pox reported in Birkenhead, and only one in any of 1 towns—viz. in Leicester. Scarlet fever showed the proportional prevalence in Salford, Edinburgh, G and Rotherham; enteric fever in Accrington, Bl Derby, and Hartlepool; and diphtheria in Burt Trent and Aberdeen. Three cases of puerperal fe notified in Salford during last month.

We are deeply grateful to those medical o health who so obligingly and regularly forward statistics as to disease-occurrences in their distr we wish we could induce their colleagues who yet responded to our appeal to follow so exact example. We confess we should much like to ominous blanks in our table filled up. May we l with the New Year, our friends, the health offic places against the names of which we have sorro put inexpressive dashes, will make an effort to : with the very moderate amount of informa which we ask, and send it to us in time for pu in the RECORD? There are difficulties no doub places. There is an overbearing or suspicious committee; or an insufficient staff; or, perhaps, i venture to hint it, an imperfect appreciation of th cance of figures on the part of the health offic The mere piling up of statistics for only vainglori of course sheer waste of time. But our tables ha and more practical objects than this. It is surel sary for us here to rehearse what those objects a tables speak for themselves, not only as disease cl also as disease forecasts.

We have strong hopes that when the notificati fectious diseases throughout the country comes w range of practical politics, whenever that desir summation may be reached, these same table may prove to the unbelievers the practical advan conspicuous economy of notification.

There is promise that even so early as next question may receive Parliamentary attention, fo as six corporations are prosecuting Bills in the to session which contain powers for the compulsor tion of infectious disease. Three of these are populous places in the north—Sunderland, Wals Wigan; three are health resorts of considerable : —Eastbourne, Ramsgate, and Southport.

Now it is worth remark that among th of defaulters in our table there are two seas both of which have possessed notification po 1879. We believe we are betraying no secret that the reason why we cannot have disease from these places, is because the local authorit would do injury to health-resorts if the es infectious disease in them became general. Surely more harm would be done to any sea by indefinite rumours which, in the absence of statistics, there are no means of satisfactorily Brighton fell into this error last year, and wit notification clauses which it had inserted in its trust that Eastbourne, Ramsgate, and Southpor more courage, and learn that in the frankest p the fullest safety.

THE Finchley Main Drainage Scheme, a by G. W. Brumell, engineer and surveyor, Finchley Local Board, has been sanctioned by the Local Government Board, and permission given to borrow money for the works, the esti of which (including purchase of land for out 60,000*l*. Owing to the peculiar feature of th is necessary to construct a sewer in tunnel 12 from its western side to the outfall site on the e The works are to be carried out forthwith. A meeting the Board marked their appreciat Brumell's services in the preparation of the : remunerating him with the sum of 175*l*., and s to his salary of 50*l*. per annum.

SPECIAL REPORTS.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

A meeting of this society was held at 1 Adam Street, Adelphi, on Friday, Nov. 21, Dr. T. Orme Dudfield, President, in the chair.

The council presented a report, stating that the council have addressed a memorial to his Royal Highness the Prince of Wales on the utilisation of the surplus fund resulting from the International Health Exhibition, recommending that the following gentlemen be elected honorary members of the society:—Colonel Sir Francis Bolton, C.E.; Captain Douglas Galton, C.B., F.R.S.; Professor Robert Koch, of Berlin; Professor L. Pasteur, of Paris; A. J. R. Trendell, Esq., M.A.

The following gentlemen, proposed by Dr. C. E. Saunders and Mr. Shirley Murphy, were elected as members of the society:—T. L. Ash, L.R.C.P. Ed., M.O.H. Holsworthy and Okhampton, R. S. D.; F. E. Atkinson, L.R.C.P. Lond., M.O.H. Craven Combined (Skipton Rural) District; H. L. Bernays, M.R.C.S., M.O.H. Charlton, Kent; A. S. Bostock, M.R.C.S., M.O.H. Whyke and Boxgrove District; H. Bullock, F.R.C.S., M.O.H. Heston and Isleworth R. S. D.; W. C. Blackett, M.R.C.S., M.O.H. Durham Rural and Brandon Urban District; J. Burke, M.D., M.O.H. Hatfield, R. S. D.; H. Butterfield, M.R.C.S., M.O.H. West Kent Combined R. S. D.; E. N. Carless, M.B., M.O.H. Devizes U. S. D.; E. Hunt Carter, M.R.C.S.E., M.O.H. Chelmsford U. S. D.; A. Clarke, L.R.C.P. Lond., M.O.H. Street U. S. D.; J. W. Cook, M.D., M.O.H. Tending R. S. D.; C. J. Denny, L.R.C.P. Lond., M.O.H. Hartley-Wintney, R. S. D.; A. L. Evans, L.R.C.P. Lond., M.O.H. 1st District Hawarden Union; H. J. Fausset, M.D., M.O.H. Tamworth U. and R. S. D.; E. F. Fussell, M.B., M.O.H. East Sussex R. S. D.; K. H. Hillard, M.D., M.O.H. Aylesbury R. S. D.; W. C. Morris, M.B. Ed., M.O.H. Chester-le-Street R. S. D.; A. A. Napper, M.R.C.S., M.O.H. Hambledon Union; C. Roberts, M.R.C.S., M.O.H. Usbridge R. S. D.; W. Robinson, M.D., M.O.H. Gateshead; F. Scott, M.R.C.S., M.O.H. Edmonston U. S. D.; W. Stamford, L.R.C.P. Lond., M.O.H. Tunbridge Wells; W. J. Sykes, M.D., M.O.H. Portsmouth Borough; E. J. Syson, L.R.C.P., M.O.H. St. Neots, Stamford, Caxton, and Whitesea R. S. D., and St. Neots U. S. D.; E. Walford, M.D., M.O.H. Ramsgate U. S. D.; T. Wheeler, M.R.C.S., M.O.H. Bexley U. S. D., and No. 2 District Darford Union; J. M. Wilson, M.D., M.O.H. Doncaster U. and R. S. D.

The following gentlemen were elected as associates of the society:—Nominated by Dr. Dudfield and Mr. Shirley Murphy—Rogers Field, B.A. Lond., M.I.C.E.; Louis Parkes, M.D. Lond.; Ernest Turner, F.R.I.B.A.; William Weaver, C.E., surveyor to the Vestry of Kensington. Nominated by Dr. Jas. Stevenson and Dr. Dudfield—Mark Judge, A.R.I.B.A. Nominated by Mr. S. R. Lovett and Mr. Shirley Murphy—George Wallace, C.E., surveyor to the district of St. Giles. A paper was read on 'Noxious Trades,' by Alfred Spencer, Esq., of the Metropolitan Board of Works, which will be published in the SANITARY RECORD of Jan. 15, with the discussion which followed it.

GLASGOW SANITARY PROTECTION ASSOCIATION.

At the third annual meeting of the members of the Glasgow Sanitary Protection Society, Sir William Collins in the chair, the annual report by the council was held as read. It stated that the past year had been one of progress and success, and the membership, notwithstanding a number of resignations, due largely to the present bad state of trade, was 343, being an increase of 28 compared with the preceding year. Of those 278 subscribed 17. 12s., and the rest (country houses, banks, public institutions, &c.) paid higher rates. The expectation expressed in last

report, that the work outside Glasgow would increase, had been verified, the work in the country having done compared with last year—about 60 coast and houses in various districts having been examined and reported on. Town work had also increased. The year 155 houses had been examined for the first and of these 115 were found to have decided defects. These varied from slight leaks in the pipes to c stoppages, and pipes with hardly any pretence at being tight. The council were pleased to observe that the Association was being largely referred to as an arbiter between lord and tenant, numerous cases having come and notice where a house was taken on condition that it was certified to be safe by the engineer of the Association. The advantage of a report from a neutral party, who have no possible interest in what might be done, was largely recognised by the public. The council could speak from experience decidedly on the necessity of annual inspection.

The Chairman, in moving the adoption of the report, the Association might almost be looked upon as a insurance company, by which members could insure the health of themselves and families for a moderate sum. He believed also that if parties, on looking out for their own safety, were to insist on the landlord giving a certificate that his house was all right, landlords would for their own sake be obliged to employ the services of the Association.

Professor W. T. Gairdner, M.D., said that a real want of such an association, setting aside the sanitary department could do for them, there was no doubt whatever. A great deal had been said about the subject. He would just mention that he had entered his house in the college for the first time built within six or seven years, at all events it was a temporary one with the new college buildings, and would reasonably have expected to find everything in a state of perfection. It so happened that he was not twenty-four hours in the house before he found something. He ultimately found a skilled man, with the result that not only his own house but the whole thirteen houses of the college, he completely overhauled again within a year or two they were built. His own house was a perfect specimen of little insanitary defects, and he didn't think much over the line when he said that it cost him 70s. or 80s. to get the errors put right. No building was therefore no security, and no man could count with comfort on his house being safe unless he joined an association like this. The professor also called attention to the great dangers that beset people at coast resorts in search of health, and remarked that of them, in taking lodgings at the coast, simply themselves into disease. It would not, he said, be reasonable if it were a stipulation in letting lodgings there should be a skilled report as to the sanitary conditions of the houses every year before they were entered.

THE COST OF CLEANSING IN GLASGOW.

THE statement of the revenue and expenditure of the Cleansing Department of the Police Board, with report, for the year ended May 14 last, has been presented by Mr. John Young, superintendent of the department. (See SANITARY RECORD for Sept. 15, p. 11.) The statement embraces all accounts under domestic scavenging or 'manure,' and public-street scavenging exclusive of the cleansing of private streets and squares. In the present balance-sheet the cost of the operations is set down at 33,780s. 7s. 11d. The cost was 35,068s. The result, therefore, is a saving of 1,287s. 12s. 11d. The expenditure under scavenging or 'manure,' or public-street scavenging estimated at 65,568s., whereas the actual expenditure was 65,290s. 7s. 3d., or 277s. 12s. 9d. less than estimated. On the other hand, the revenue, which was estimated at 30,500s., is now shown to have reached 30,210s. 2d., or 1,010s. 2d. in excess of the estimate.

sent balance cost exceeds the figure for the previous year by 606*l*. This is more than accounted for by the fact that the revenue for the year just ended is 997*l*. under the previous year's revenue, a result caused by the increasing difficulty experienced in making sales of manure. The expenditure has been 391*l*. less than during the previous year. The total amount of sales and charges, including railway carriage, but *minus* deductions, is 31,503*l*. 1*s*. 8*d*. Of this sum 18,386*l*. 5*s*. 1*d*. is for net sales of manure—12,189*l*. 1*s*. 6*d*. for 'city,' and 6,197*l*. 3*s*. 7*d*. for 'long.' The sales effected by agents amount to 8,661*l*. 10*s*. 6*d*., and by the staff of the department 9,724*l*. 14*s*. 7*d*. The balance is made up by railway carriage (recoverable from consignees) and other smaller charges made for goods sold and work performed. The uncollected accounts amount to 4,811*l*. 4*s*. 11*d*., and the unpaid accounts to 6,003*l*. 3*s*. 9*d*. The bad debts written off during the year amount to 24*l*. 5*s*. 11*d*. On the capital account the department is charged interest at the rate of 3½ per cent. per annum, with the exception of the Fulwood Moss item, on which interest is charged at the rate of 5*l*. 13*s*. 8*d*. per cent. The total amount of this account up till May 15, 1883, is 95,921*l*. 9*s*. 8*d*. The additional payments during the year were as follow:—Crawford Street despatch works, 5,236*l*. 11*s*. 6*d*.; St. Rollox workshops, 803*l*. 2*s*. 5*d*.; erect orderly bins, 431*l*. 5*s*., which, with a sum of 27*l*. 3*s*. 4*d*. unpaid at May 15 last, gives a total of 13,119*l*. 11*s*. 11*d*. The daily average number of men actually at work under Mr. Young's management during the year has been 771. The number of stud at May 15, 1883, was 173, as against 179 at May 15 last. The average cost of feeding and litter during the year has been at the rate of 13*s*. 2½*d*. per horse per week, as against 14*s*. 8½*d*. in the previous year. The stock of dry manure on hand at May 15, 1883, was 12,219 tons 12 cwt. During the year there have been removed 185,695 tons 12 cwt. The total domestic refuse collected during the year has exceeded the figures for the previous year by 1,497 tons. The average cartage per working day during the year was 727 tons, exclusive of street watering. During the year there were 53,236 loads, or 17,567,880 gallons of water spread over the streets and roads of the city. During the year there were 210 men employed daily cleansing private streets and courts, and the cost for wages and material has been 10,530*l*. 6*s*. 2*d*. The estimated cost was 9,890*l*. The excess is accounted for by extra work done, chiefly in hose-washing, which was authorised on August last, after the estimates had been made up. The total expenditure under Mr. Young's management during the year has been as follows:—Cleansing—Manure and scavenging, 65,290*l*. 7*s*. 3*d*.; cleansing of private streets and courts, 10,530*l*. 6*s*. 2*d*.; extraordinary expenditure (capital account), 17,198*l*. 2*s*. 3*d*.; public conveniences, 165*l*. 18*s*. 10*d*., and adding total revenue, 31,510*l*. 5*s*. 2*d*., the total amount dealt with during the year amounts to 124,694*l*. 14*s*. 8*d*.

THE NEW FIRE-PROOF BUILDINGS AT ST. PANCRAS WORKHOUSE.

A NEW block of buildings for the enlargement of St. Pancras Workhouse is now being erected at Cook's Terrace, from designs by Mr. H. H. Bridgman, architect, 2 Poultry, E.C., which, when completed, will be unique in workhouse arrangements, as providing a great safeguard against fire and consequent panic. This new addition will consist of four floors of wards, each 80 feet by 40 feet, two wards on each floor, with staircase, lift, and attendants' rooms between them, a ground-floor appropriated to administrative purposes, and an upper central story of nurses' rooms, together with wings at the extreme ends or baths and water-closets—in all six storeys. The floors throughout are constructed on the 'ligno-concrete' system, by Messrs. Clark, Bunnett, & Co., and while being proof against fire from floor to ceiling, although only 6, 7, and 3 inches thick respectively, also appear perfect from a

sanitary point of view. Mr. Bridgman aptly remarks 'That if the example of the St. Pancras guardians and other bodies having control over the erection of public buildings were followed of first obtaining a report, or receiving suggestions from Captain Shaw, the chief officer of the Metropolitan Fire Brigade, by placing the plans of the intended erections before him, as has been done in this case, we should soon cease to hear of the differences and conflicts in regard to altering and adapting existing buildings to meet the requirements of public safety, and fewer, if any, of the disastrous fires and panics that are continually occurring. If, moreover, it were made imperative to obtain such reports, and to act upon them, the satisfaction would be still more complete.' Capt. Shaw's report has been printed, and in it he expresses his approval of the evident care and attention which have been bestowed upon the smallest details likely to assist in securing immunity from fire, or, in the event of its occurring, preventing it extending to serious proportions, as well as with the ample measures provided for its extinction. Captain Shaw, however, suggests that additional staircases may be provided at each end of the building in addition to the central staircase, so as to secure additional means of exit in case of fire or alarm. It is stated that these suggestions will be carried out. It is gratifying to find that the guardians of St. Pancras are so fully alive to the necessity of taking measures to provide for the security of life and to fulfil sanitary requirements. It is to be hoped that their enlightened example will not be unmarked, as in the ligno-concrete manufactured by Messrs. Clark, Bunnett, & Co., there would appear to be a material at command of a very useful character and one deserving of extensive trial.

THE METROPOLITAN PUBLIC GARDEN, BOULEVARD, AND PLAYGROUND ASSOCIATION.

THE ordinary monthly meeting was held at 83 Lancaster Gate, on Dec. 2, Lord Brabazon in the chair. A grant of money was voted towards the improvement of Ebury Square, Pimlico, which the association is maintaining as a garden, and progress was reported with regard to several important pieces of work now in hand, such as the laying out of St. Bartholomew's Churchyard, Bethnal Green, the formation of a gymnasium at St. Philip's, Stepney, and the preservation of Highgate Woods and of certain disused burial-grounds in Farringdon Street, E.C., Union Street, S.E., and Mount Street, W. The new work taken in hand included the proposed planting of trees in Mile End Road, placing of seats at Christ Church, Westminster, laying out of Carlton Square, Mile End, as a public garden, and opening of gardens in Stepney, Camden Town, and Upper Holloway. On the representation of the Rev. W. Robinson the association undertook to provide a caretaker for six months for the churchyard of St. Mary's, Whitechapel. Several other matters engaged the attention of the meeting, and the second annual report was laid before the members.

PENNY DINNERS.

A CONFERENCE of School Board Managers and Teachers was held at the Society of Arts, Adelphi, on Saturday, Dec. 6, to consider the subject of penny dinners in connection with underfed children. Mr. Sydney Buxton, M.P., presided.

Mr. H. Forbes Clarke, the Secretary of the Sub-Committee of Representative Managers, read a statement of which the following is a summary:—The sub-committee was appointed in June last to consider the subject of cheap dinners in connection with the children attending Board Schools. In August they issued a circular to the representative managers of each school (see SANITARY RECORD for Sept. 15, 1884) to which they have received twenty-nine replies. At the present time fifteen penny dinner centres are in operation, and a dozen or more are in contemplation. As an illustration of the dinners which can be supplied, the following list is given of the dinners

already provided at Albany Place, Hornsey Road, Holloway. The quantities are, as a rule, found quite sufficient by the children. The prices stated are for one hundred dinners, and include the cost of fuel and cooking; no rent is paid. 1. Currant pudding, bread and jam, 8s. 9½d. 2. Suet pudding and jam, bread and cheese, 8s. 10d. 3. Rice (with suet), milk and treacle, bread and jam, 8s. 9½d. 4. Soup (two sheep's head and barley) and bread, 6s. 6d. 5. Potatoe soup (with bones) and bread, 8s. 2d. 6. Bacon (hot) and beans and bread, 8s. 3½d. 7. Bacon (hot) and potatoes, bread, and jam, 8s. 10½d. 8. Irish stew and bread, 6s. 11½d. 9. Soup, and dumplings, and bread, 8s. 1½d. 10. Pea-soup and bread, 7s. 8d. 11. Mutton broth, bread, and jam, 7s. 3½d. 12. Meat, roly-polly, bread and jam, 9s. 1½d.

It will be seen that the dinners differ in cost, but as one of the committee writes, 'by alternating the more and the less expensive, a mean is maintained for the week.' The cost will vary a little in different districts, according to the sums paid for food and for incidental expenses.

The Chairman said he was pleased to see such a very large attendance, which showed that the subject for which they had met had acquired great interest. The question of penny dinners had only lately become urgent, owing to the large amount of public interest that had been drawn to over-pressure in schools; and he thought that the primary cause of such over-pressure could be traced to insufficient food, in fact that 'over-pressure' was merely another word for underfeeding. His hearers would agree that the Education Department ought not to interfere in the matter. He was glad to welcome Mr. Mundella, who did not come to the meeting in his official capacity.

Although the School Board could not take any active part in the penny dinner movement, the members might lend the schoolrooms, free of rent. He pointed out that of these dinner centres fifteen had already been started, and that twelve were in contemplation, and although some of them might not yet be successful, that was no reason why others should not be started, as at present the movement was really only in an experimental stage, and he had no doubt but that in time the dinners would be quite self-supporting.

Mr. H. Spicer, member of the London School Board, said that for twenty years he had worked in ragged and other schools, consequently he knew something of the lack of food spoken of. Children had come to him, for whom the first thing requisite was something in the shape of a meal; many had come there without a breakfast and gone through the day without anything, not knowing whether they would find food when they got home. He urged that this was not a question either for the Education Department or the School Board, but that it could be solved by voluntary agency. He then moved the following resolution:—"That it is expedient to form a Central Council to assist the Local Committees who have engaged, or are about to engage, in providing penny dinners on a self-supporting basis." The Rev. J. H. Rose, in a few words, seconded the resolution, which was adopted.

Mr. Mundella, M.P., supported the resolution. He said the question of feeding the children was a more important one than the education question itself, although he did not undervalue education, which was the greatest factor in the future raising of our population. But there was a larger question behind it. We had in our great cities and towns, and especially in London, a class which might in itself almost be considered a caste, which consisted of unskilled labourers who had no regular occupation, but lived from hand to mouth; a number of them were the product of intemperance and a great proportion were steeped in misery. He thought it was a social scandal that no such squalor and misery is to be found in Europe as there was in London, and the only way to wipe out this blot was to train the children. He spoke of the school system in Switzerland where the rich children took the poor children home to feed them. He particularly mentioned two schools in England which had achieved

great success. One was a Devonshire school w Henry Peek (the first organiser of penny dinners five years carried out that system with remarkable success. The other was the Jews' Free School, Spitalfields; 3,100 poor Jews, most of them foreign refugees, 3,200 on the rolls, attend daily, and there is no pressure there because the Jews of the West End after the Jews of the East End. (See page 247.)

He had been to see his friend the Rev. Mr. Moore Ede had provided penny dinners at Tyne; he was present recently when 150 to 200 children to dinner, which the children seemed to thoroughly enjoyed. The food was very good; in fact he tasted some soup, which was better than some he had at York for a shilling.

A resolution was then proposed by the Rev. Barnett, that the following ladies and gentlemen Central, Council for establishing self-supporting dinners in connection with elementary schools Geo. Hamilton, Lady Stevens, Mrs. Maitland King, Mr. W. Bousfield, Mr. H. Forbes Clarke, S. D. Fuller, Mr. H. Hoare, Rev. J. H. R. H. Spicer, Major J. Wade, with power to add number. An amendment was proposed by Mr. I member of the London School Board, and can Mr. Lucraft's and Mr. Murphy's names be added Mr. Mundella, M.P., consented to act as president and Mr. Sydney Buxton, M.P., as vice-president central council.

The Rev. Mr. Moore Ede seconded the resolution was adopted. He gave an account of what he had in connection with these penny dinners in his (Gateshead), where he had provided 13,180 dinners cost of 48l. 2s. 6d. After paying all expenses a balance left of 6l. 10s. 9½d.; he could provide at a decidedly less cost than 1d. per head. He the soup which Mr. Mundella praised so much cost for 30 gallons, and if the cost of bread were added 50 pence, it would cost 125 pence to feed 180 children.

In reply to a question, Mr. H. Forbes Clarke average daily attendance at Gifford Street for the weeks was as follows:—97, 130, 157, 157, 217, :

THE *Fish Culture Journal* describes a curious experiment made at the aquarium of the National Fish Association at the Heath. It had been requested by the Association, on the authority of some American brandy would revive fish on the point of death, maiming too long out of water, and the secretary to test the truth of the assertion. Two Pruss were therefore taken from the tank at the aquarium kept in the air for four hours. At the end of the little brandy and water was administered to one with a feather, and both were then put back into the tank. The fish which had been dosed with brandy revived, but the other floated about on its side, as dead; and to avoid contaminating the water, suppose, it was taken out and thrown aside. The second, however, taking up the lifeless fish, opened its mouth, poured brandy and water down its throat, and floated again in the tank, but with little expectation of revival. For five minutes it floated motionless, but slight evidence of life appeared, and the fish soon to move its fins feebly, and regained by degrees its strength. Neither of the fishes suffered, apparently permanent injury from their experience. This disappointing; born water drinkers like fish should not have conducted themselves differently, and to the pernicious effects of alcohol under all circumstances. We remember reading of some pigs, those much used animals, which, when dosed with alcohol, behaved in a manner which has been expected of them, and rendered them liable to a fine of five shillings or equivalent imprisonment.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

'Something attempted, something done.'

BEDFORD RURAL.—A noteworthy feature of this report is the account which it contains of the efforts of the sanitary authority to improve the homes of the poorer inhabitants. Few bodies similarly circumstanced can lay claim to a course of action which for a period of eleven years has been so steadily and successfully pursued. In referring to the subject Dr. Prior observes: In these days, when the great and the wealthy are vying with one another to evince their solicitude for the improvement of the dwellings of the working classes and of the poor, it may be as well to let it be known that this work has, for the past eleven years, been strictly kept in view. During that period 186 houses have been reported to the sanitary authority as unfit for habitation, of which some have disappeared entirely, some have ceased to be used as dwellings, some have been enlarged, repaired, or added to—rendered habitable, in fact; and though there still remain many others which are far from being perfect, the representations of the officials have been controlled by a sense of the losses to which agriculture has been exposed, and the additional accommodation required for some of the families whom it has been necessary to remove. Thus the houses reported as unfit for habitation have latterly been, on the average, about twenty annually, while in the first three years they only averaged nine. Overcrowded houses, on the contrary, have diminished materially in number, and it is now thoroughly known in the villages that this form of nuisance, injurious to health and repulsive to decency, can no longer be continued, and the usual subterfuges and excuses have been too often tried in vain to leave much hope of success. As a consequence, the annual average of cases of overcrowding has diminished from 14 per annum in the first three years to between 7 and 8 in the last eight years. There was an increase in the general death-rate, which, however, was not due to the prevalence of any unusual conditions, but rather to the large proportion of aged persons among the population. Diphtheria, which was fatal in nine cases, seems to be establishing itself in the district, whilst, on the other hand, typhoid fever was not nearly so fatal as in the previous year. The zymotic death-rate is estimated at 1.8 per 1,000, which is slightly in excess of that returned for 1883.

BRAINTREE RURAL.—The third annual report of Mr. C. E. Abbott possesses the conspicuous merit of being written strictly on the lines of the official instructions. The circumstances of the district are such as to call for active and energetic supervision, and the report bears evidence of this having been bestowed. The system of excrement disposal at Coggeshall is in much need of improvement, which could best be effected by the adoption of the Health Officer's suggestion for the establishment of the Goux system of closets. The water supply for the most part is derived from shallow surface-wells, which are not fit receptacles for drinking-water. The necessity of securing an improved supply was demonstrated by the contamination of one of these wells by typhoid excreta. The year was characterised by a considerable prevalence of zymotic disease, some 140 cases being notified to the Health Officer. Scarletina, the continuation of the epidemic of 1882, was scarcely absent from the district at any time, and caused fifteen deaths. The disease was of a mild type, and the spread of infection was largely due to this and to the reckless exposure of children when in a state of desquamation. Diphtheria, also the revival of the outbreak of the previous year, was fatal in eight cases out of a total of twenty-eight, of which information was received. Mr. Abbott is inclined to attribute the principal part of the epidemic to school influence, though he admits that a more probable explanation is to be found in the extreme poverty, bad feeding,

and unhealthy conditions so prevalent in some parts of the district. Nine deaths were recorded from diarrhoea, and three from measles. Proper precautions were adopted to prevent the spread of these diseases, which in all numbered thirty-six, being equivalent to a death-rate of 1.75 per 1,000. The general death-rate is returned at 16.69 per 1,000.

CARTON.—Mr. J. T. Knight reports that a larger number of private improvements were effected in 1883 than in the previous year, but he reminds his authority that much more might and ought to have been done, and he earnestly recommends a more vigorous exercise of the powers conferred upon them by the Public Health Act. Particular attention is drawn to the necessity of a supply of wholesome water, and to the fact that some parts of the district are deplorably in need of proper sewerage. On the whole, however, much has been done of late to improve the sanitary aspect of the district, and the report shows that the efforts of the sanitary authority are often seriously hampered by private interests. The mortality from all causes in 1883 was much less than in the previous year, and the zymotic deaths exhibited a decrease of 13. The fatality amongst infants, however, was extremely high, and chest affections contributed somewhat largely to the death-rate, which is estimated at 16.03 per 1,000.

CARNARVONSHIRE COMBINED DISTRICT.—The almost phenomenal prevalence of whooping-cough in this district during 1883 is naturally a subject to which Mr. Rees, in his annual report, devotes much attention. For the most part the disease, which caused 211 deaths, was spread by the ignorance and apathy of parents, and the absence of means for obtaining information of new cases. An effort was made to secure the compulsory notification of such cases, but without success; and, pending some satisfactory arrangement, Mr. Rees advocates the erection of infectious hospitals. It would appear, he observes, that this question is somewhat at a deadlock, from the different views regarding it held by the local and central authorities. The former hesitate to incur the expense of building hospitals without having prompt information of the first cases invading their districts, a condition which they look upon as essential to its usefulness, and the latter are reluctant to grant compulsory notification until the erection of a hospital has shown that there is a thoroughly earnest resolution to deal effectually with the cases when they have been notified. Mr. Rees inclines to the view that, even in the absence of hospitals, the notification of infectious disease is invaluable, though he admits that for realising its utmost advantages the provision of such accommodation is essentially necessary. Diphtheria and croup contributed largely to the mortality, the deaths numbering 73, whilst on the other hand the fatality from typhoid fever was much below the average. This last disease visited Bangor with remarkable leniency. Three cases only came under consideration during the first six months, and all recovered. When the enormous amount of infective matter that was diffused through the town in 1882 is taken into consideration, it appears little less than marvellous that the disease should have been stamped out so effectually. Mr. Rees attributes this to the thorough and constantly sustained disinfection, especially in keeping the sewers constantly filled with euechlorine gas. Measles and scarlatina were both prevalent in epidemic proportions, and together destroyed 137 lives. The death-rate from zymotic causes was as high as 3.14 per 1,000, the general death-rate being equivalent to 20.4 per 1,000.

FULHAM FEVER HOSPITAL.—In his seventh annual report on the working of the Western Hospital of the Metropolitan Asylums Board, Dr. R. D. R. Sweeting, the medical superintendent, states that including the patients remaining at the close of 1882, 273 patients were discharged cured, 21 died, leaving 43 still under treatment. Of the 236 admissions in 1883, as many as 197 (83 per cent. of the whole) were suffering from scarlet fever, 18 from enteric fever, 13 from typhus, and 8 from other

diseases. Besides these, six cases of scarlet fever developed eruptions of German measles in their course, the infection being started either directly from one of the cases admitted with the disease, or being due to the concurrent infection of one or more outside. Two cases, also, of chicken-pox co-existing with scarlet fever were noticed, one in which the eruption of the former was just showing, and in the other was in a more advanced stage; these cases infected a scarlet fever convalescent. Fifty-eight per cent. of the total admissions of scarlet fever were under ten years, whilst the second quinquenniad afforded the most cases. The deaths numbered 15, the mortality being greater amongst males than females, and heaviest in those under five years. Amongst the kidney affections noted by Dr. Sweeting as complications and sequelæ of this disease, acute inflammation and simple albuminuria held equal positions, being equal to a percentage of about 12 on the total of completed cases; dropsy was all but absent. Bronchitis and pleurisy were the most frequent amongst lung complications; the cervical glands the most frequently enlarged; purulent otorrhœa was fairly frequent; also purulent nasal catarrh. Uræmic convulsions were noted in eight cases, and a true relapse in ten. Acute rheumatism figured as a complication four times; and there were three cases of abscess behind the pharynx. Of those noted in enteric fever, which was fatal in three instances, and exclusively amongst males, bronchitis and pleurisy were the most common. There was no mortality amongst the patients suffering from typhus fever; indeed, as a matter of fact, five only were treated, the others being transferred. The average duration of stay of scarlet fever cases was 78·5 days, but this average was increased by the prolongation of stay of the patients who contracted measles. That of enteric fever cases was 72·2 days. Five of the nursing staff and one maid were attacked with scarlet fever, but none died: all were first attacks. An assistant nurse contracted typhus fever and died; two others caught measles and enteric fever respectively, and recovered. Dr. Sweeting's report, which maintains the high character of its predecessors for method and arrangement, concludes with a number of useful statistical tables, those recording the complications and sequelæ observed in completed cases of scarlatina and enteric fever being particularly interesting.

GLANFORD BRIGG RURAL.—The recent disclosures at Liverpool and elsewhere invest with a special interest the traffic in life insurance policies, and Mr. Moxon, in a report which evinces much care and thought, properly takes exception to the dangerous plan, extensively carried on in several villages in his district, of insuring the lives of infants and children. Zymotic diseases were fatal in 1882 to 65 persons, equal to a death-rate of 2·25 per 1,000. Mr. Moxon advocates the establishment of infectious hospitals in the more populous parts of his district, being convinced that many of the inhabitants would gladly take advantage of the opportunities thus afforded for the treatment of disorders of this kind. Diseases of the respiratory organs accounted for 65 deaths, a mortality considerably augmented by injudicious exposure. Passing over the principal social causes favouring consumption, over which a sanitary authority can exercise but little control, Mr. Moxon thinks that the stringent enforcement of by-laws having reference to the construction of better ventilated and drier houses ought in time to bear fruit. The general death-rate for the whole of the district represented 16·5 per 1,000. During 1883 the number of deaths from phthisis was 13 above the average. Mr. Moxon is unable to account for this excess, which he thinks may in part be an accidental circumstance, and he hopes that the present year may exhibit a corresponding decrease. This mortality was one of the causes of the increased death-rate, which was equivalent to 19·0 per 1,000. The fatality amongst infants and young children was below the average, but there was a large number of deaths recorded in aged persons. Zymotic diseases destroyed 81 lives, representing a death-rate of 2·8 per 1,000.

GLOUCESTER URBAN.—The sanitary authority of this town seems in no mood to carry out the important requirements of their district. The fault, however, does not lie with the health-officer, Mr. J. P. Wilton, who from year to year continues to remind them that there is much to be done. Speaking of the condition of the sewers he observes:—'In the report for 1877, I stated that the escape of gas through the ventilators was a cause of serious complaint. In my report for 1880 I spoke of the nuisance arising from this cause, and in my last report I again called attention to the subject. At the present time there has been but little abatement, and as the warm weather arrives I anticipate a renewal of the nuisance.' Mr. Wilton points out that where additional ventilators have been provided the results have always been satisfactory, and he urges his authority to largely adopt this plan. An appeal is also made for the provision of proper hospital accommodation, the present building being described as 'a second-hand, wooden structure, which is now becoming old, and is not perfectly weather-proof.' That an erection of this kind should be called upon to serve a population of nearly 40,000 inhabitants seems scarcely credible, and the town council will be incurring a grave responsibility if they continue to allow their district to remain unprovided with adequate means for treating cases of infectious sickness. Mr. Wilton has little interest to say in regard to the mortality statistics, but he thinks that, with the exception of the continuance of the epidemic of scarlet fever, the health of the town has not been unsatisfactory. Chest affections contributed largely to the death-rate, which is estimated at 17·3 per 1,000.

HANLEY.—A large proportion of this report is taken up by Dr. Swift Walker with statistics to show that the increase in the general death-rate from 22·3 to 24·1 per 1,000 was entirely confined to children under five, and to adults having ages exceeding forty-five years. Of the 401 deaths of infants under twelve months, 91 arose from the various zymotic diseases (52 alone being attributed to diarrhœa), 32 from tubercular diseases, 74 from convulsions, 71 from diseases of the respiratory organs, 55 from atrophy and debility, and 31 were premature births. Comparing these numbers with those of the previous year, it is found that the deaths from zymotic causes, constitutional diseases, and atrophy and debility show an increase, whilst those from other causes exhibit a decline. From the principal zymotic disorders no fewer than 219 persons at all ages lost their lives, returning a death-rate of 4·4 per 1,000; and Dr. Walker thinks that 'considering we have been visited by three epidemics, it seems almost miraculous that the rate of mortality is not higher.' The outbreak of scarlet fever, fatal in 65 cases, seems to have caused considerable trouble; but the report contains little of interest in regard to this or the other epidemics. Some sanitary work of a practical and permanent character was performed during the year, although Dr. Walker's method of recording it is not of the best.

HELMSLEY RURAL.—In addition to enjoying a remarkable immunity from zymotic disease, the general death-rate of this district during 1883 (13·88 per 1,000) was much below the average of previous years. The mean death-rate recorded in the period 1863–1880 was 18·7, whilst the average of the last three years was only 15·2. Dr. Bruce Low estimates that this is equal to a saving of 14 lives per annum, which he attributes to the improved sanitary condition of the district. The rate of infantile mortality also participated in the decline, although the fact that four out of nine deaths under one year occurred in illegitimate children cannot be regarded as satisfactory. Scarlet fever was the only infectious disease which appeared in a fatal form, the deaths (three in number) being equivalent to a zymotic rate of 0·75 per 1,000. There were several local outbreaks of diarrhœa, due principally to insanitary surroundings; but not a single case of either diphtheria or enteric fever was heard of. Dr. Low is unable to chronicle the completion of any works of drainage or water-supply, and he points out that the machinery for

h outbreaks of infectious disease has practically ce in the district. He thinks, however, that ity are to be congratulated on the satisfactory e year's work, and hopes that the future may rovision of proper means for protecting and g the health of the inhabitants.

M RURAL.—The most pressing requirement of tant mining district is a wholesome supply of ch, owing to the obstinacy of the local water the authority are unable to provide. Dr. Mac- ts out that the absence of this first essential of anliness was severely felt at Prudhoe, where a ber of cases of typhoid fever occurred either indirectly from this cause. The fact that no ts whereby the excellent drainage throughout a of the district may be systematically flushed, y anticipation of these villages being placed in isfactory condition. The history of the circum- ending the prevalence of zymotic disease, which for 13·9 per cent. of the total deaths, as com- 7·2 in the previous year, clearly shows that e cases might have been prevented, had imma- nation of their occurrence been afforded to the icials. Unfortunately, however, no means exist any knowledge of the first appearance of in- ease can be given to the health-officer, at least a can be in all cases depended upon. Dr. Mac- not repeat the many arguments in favour of a notification, but he observes that until this has ded, the difficulty of dealing successfully with will be almost insuperable. There was a de- rate of infantile mortality, and the uncertified e fewer than in 1882. Dr. MacLagan seems to cted no opportunity to improve the sanitary ie district, and his report contains much evidence and painstaking work.

DREST RURAL.—To judge from Mr. Jenkins' ort, the general sanitary condition of this district have materially improved during 1883. In the a no death has taken place from typhoid fever uthority appointed a Committee of Inspection, d upon the improvement of the drainage and ly. At Lyndhurst a committee was appointed ite the sanitary condition of the place, with the se the words of the medical officer himself, 'of rectifying the defects as far as is possible at It is also satisfactory to note that the inhabit- is place have appointed a burial board, and site for a burial ground. Some such committee ch sat at Lyndhurst is evidently wanted in the trict, where the death-rate is the highest in the l the water-supply and drainage are very de- at Hilltop every house was inspected, and all te sanitary improvements carried out. The or the year 1883 was 27·85, and the death-rate f zymotic diseases, measles proved by far the accounting for 13 deaths out of the 16 attributed disorders of its class. Of the 13 deaths from 2 occurred at a village named Eling, which close proximity to Southampton, where the raging, and whence it was probably carried. r of deaths in children under 5—73 out of an of 211, or 5·5 per 1,000 population—was greater uld be. In Mr. Jenkins' opinion the cause is l, in a great measure, in the scarcity in many milk, and in the custom which prevails among giving their infants 'farinaceous or other unsuit-

HAM.—Based upon a population of 54,063 per- eath-rate of this district in 1882 represented 000 against 16·8 in 1881 and 16·5 in 1880. is increased mortality was due to the fatal pre- zymotic diseases, which accounted for 216 4 per 1,000 inhabitants, out of a total of 973 from all causes. Scarlet fever and whooping- e present in epidemic proportions, and together

destroyed 116 lives; while diphtheria, measles, and 'fever' claimed a larger death-rate than in the previous year. The very unsatisfactory state of the sewers, especially as regards flushing and ventilation, is an evil of great magnitude, and one that the authority should bestir themselves to remove. Referring to the need of an extension of the sewage works, Dr. Watson observes, 'I hope that the Board will liberally provide engine power, not only for the present increased requirements, but for the future, as I understand that the present engine and pumps are at times totally inadequate to lift the sewage, and at such times the sluice has to be opened to allow the crude sewage to pass off into the dock.' Both in this and in other directions the district stands in need of earnest and sustained attention at the hands of the authority, whose dilatory action cannot be excused on the plea of want of practical advice. During 1883 Dr. Watson reports that many unhealthy places have been greatly improved, although the state of the sewers is still very defective. There was a change for the better in the system of re-use removal, and, as regards the performance of minor sanitary work, Dr. Watson notes with satisfaction that owing to the readiness with which owners and occupiers of houses complied with the requisitions and notices served on them in respect to nuisances, it was unnecessary to take legal proceedings in any case. The general death-rate represented 16·1 per 1,000, being, with one exception, the lowest recorded since 1871. There was an extensive epidemic of measles which destroyed 41 lives, and the mortality from diphtheria was much above that registered in the two previous years, whilst on the other hand scarlatina, whooping-cough, and 'fever' were less fatal than usual. The zymotic death-rate was equivalent to 2·7 per 1,000.

SURVEYORS' AND SANITARY INSPECTORS' REPORTS.

BARROW-IN-FURNESS.—Mr. W. H. Fox, C.E., the surveyor and engineer of this borough, has written an excellent and practical report as to his proceedings during the year ended Aug. 31 last. Not the least interesting part of the report is that which is devoted to an account of the single and duplicate systems of sewerage at present in use. Referring generally to the question of drainage, Mr. Fox is convinced that every year brings additional evidence that sanitary matters are being better understood and appreciated, an increased anxiety being noted on the part of the inhabitants to have the drainage of their houses put in order. This is not always easy, for after the old drains have, it is believed, been taken up and relaid and properly disconnected from the house, there is still some defect, which is at length found to arise from an old field drain or a house drain abandoned some years previously, and which had not been properly cut off. Much attention is devoted to an account of the steps taken for improving the surface of back yards, and we quite agree with Mr. Fox in thinking that a paving of Macadam is to be preferred to the old and objectionable cobbles, which permit of the lodgment of filth in a manner that is difficult to remove. Proper regard was had to the regular and systematic flushing of the sewers, especially in the summer, and a sharp look out was kept on all new buildings. The removal of refuse was not neglected, and the surveyor records the mortality statistics of the borough since 1874 in order to emphasise the advantages of the water-closet and dry-ashpit system over the old-fashioned middens. The appendix contains an abundance of statistics of local importance, together with some useful maps and plans.

BEDFORD RURAL.—Mr. Adams reports that in 1883 he disposed of 270 nuisances, of which no fewer than 175 arose from accumulations of refuse and defective privies. Twelve houses were found to be dilapidated and unfit for

habitation, 11 were reported as overcrowded, and 20 were disinfected. In 39 cases defective drains and privies were remedied, and other minor improvements effected. Of the 270 nuisances inspected, 170 were abated without the issue of formal notice.

BOSMERE AND CLAYDON RURAL.—Mr. Harrington reports that during the past year 215 nuisances were reported, of which 192 were abated, involving the issue of 184 notices. No improvement was made in the water-supply of the district, with the exception of the closure of a polluted well; but 48 privies were repaired and otherwise improved, and 19 house drains were trapped. Altogether 1,864 houses and premises were inspected, and a considerable number of nuisances of a kind incidental to a rural district were satisfactorily disposed of. In no case was it necessary to resort to legal proceedings.

BRIDGWATER.—The report prepared by Mr. G. B. Laffan on his work in this district during 1883 is one of the best that has come before us. It sets out in clear and concise language the steps taken for improving the water-supply, describes the effect of the various sanitary operations carried out during the year, refers to the operation of the Food and Drugs Act, and concludes with some excellent and practical suggestions. Thus, he points out that owing to the situation of many of the slaughter-houses, it is almost impossible to keep them in a proper condition; and recommends the erection of an abattoir, which would not only effectually rid the district of nuisances of this kind, but prevent the traffic in diseased meat. The importance of providing public baths is also pointed out, and the authority are reminded that this is a necessity for which all progressing towns are providing. The fact that out of 119 samples of well-water analysed during the year no fewer than 79 were condemned as unfit for drinking or domestic purposes points to the need of an extension of the public service, which is being carried out. It not infrequently happened, however, that the inhabitants refused to avail themselves of this supply when provided for them. A house-to-house visitation revealed the existence of so many grave defects, notably in the dwellings of the poor, that the inspector suggests to the authority the advisability of appointing an additional officer to assist in the work.

CHESTER.—A large amount of practical work seems to have been accomplished in this district during 1883, although Mr. Wharton, the sanitary inspector, has been content to record it in the form of a statement. In regard to structural alteration in the drainage of houses, and in the management of the scavenging department, the health-officer thinks that much credit is due to Mr. Wharton for his energy and tact. As to the latter he has succeeded in reducing what was at one time an annual deficit of 300*l.* to a balance on the right side, and at the same time he has got rid of the depôts which were an expense and a nuisance. As many as 1,407 notices were issued for the performance of various works in dwelling-houses, &c., but with what result does not appear. Forty-eight houses were disinfected, and 466 were cleansed, repaired, and limewashed; 230 drains were trapped or ventilated, and 43 privies were converted into water-closets. The total number of premises, &c., inspected during the year amounted to 6,030.

DUNMOW RURAL.—After recording, in chronological order, the legal proceedings taken in 1883 for the enforcement of necessary sanitary requirements, Mr. J. Hamilton proceeds to summarise the number and nature of the nuisances abated by him during the year under notice. Although but few structural works were undertaken by the authority, the district seems to have been kept under constant supervision. Of the 226 nuisances disposed of by Mr. Hamilton, 70 arose from foul privies, urinals, and cesspools, 30 from imperfect drains, 10 from want of proper privy accommodation, and 60 from accumulations of refuse. Three houses were found to be in an over-

crowded state, two were condemned as unfit for tation, and 60 were disinfected after the existence of infectious disease.

EPHING RURAL.—A large amount of minor sanitary work was performed in this district during the year, though Mr. Bell does not make the most of it in his report. He states that he made 936 inspections, issued 300 letters, and issued 71 notices to sew houses under the Public Health (Water) Act. There were 255 served during the year, of which 47 were to improve the water supply, 60 to connect the house drains with the main sewer, 50 to open, cleanse, or reconstruct to empty cesspools, 43 to provide stretch traps and to disconnect sink pipes, and 41 to remove accumulations of refuse. Mr. Bell does not, however, as a result of the issue of these notices. Fifteen as well water were submitted for analysis, and 13 were connected with the sewers.

HACKNEY.—The report which Mr. J. Lovegrove, chief surveyor, sends us of his work in this borough is a model of its kind, and has been prepared with much care. In addition to recording the more important items of sanitary progress, so far as concerns the borough, Mr. Lovegrove goes into the question of expense, compares the cost of the principal works in one year with others, and in cases where striking differences proceed to explain how they arose. The report contains the surveyor's views on the principal bills of the year, the Thames Crossings Bill, and other matters of interest to the Vestry. Some idea of the works devoted to sanitary improvement in Metropolitan areas may be gathered from the fact that in 1883 as much as 5,082*l.* was expended in watering the Hackney district, and 10,000*l.* in new paving works. The street-lighting cost 8,932*l.* as compared with 11,758*l.* notwithstanding that 541 additional lamps had been erected. Considerable progress was made in the improvement of the sewers, re-numbering houses, and re-naming streets, and in effecting other structural improvements.
